Abstract

The Ruijsenaars-Schneider systems are ‘discrete’ version of the Calogero-Moser (C-M) systems in the sense that the momentum operator $p$ appears in the Hamiltonians as a polynomial in $e^{\pm \beta'} p$ ($\beta'$ is a deformation parameter) instead of an ordinary polynomial in $p$ in the hierarchies of C-M systems. We determine the polynomials describing the equilibrium positions of the rational and trigonometric Ruijsenaars-Schneider systems based on classical root systems. These are deformation of the classical orthogonal polynomials, the Hermite, Laguerre and Jacobi polynomials which describe the equilibrium positions of the corresponding Calogero and Sutherland systems. The orthogonality of the original polynomials is inherited by the deformed ones which satisfy three-term recurrence and certain functional equations. The latter reduce to the celebrated second order differential equations satisfied by the classical orthogonal polynomials.

1 Introduction

Exactly solvable or quasi-exactly solvable multi-particle quantum mechanical systems have many remarkable properties. By definition, the entire (or a part of the) spectrum and the corresponding eigenfunctions are calculable by algebraic means. The corresponding classical systems share also many ‘quantum’ features. For example, the frequencies of small oscillations near the classical equilibrium are ‘quantized’ together with the eigenvalues of the
associated Lax matrices at the equilibrium. These phenomena have been explored extensively for multi-particle dynamics based on root systems, in particular, for the Calogero and Sutherland systems \([1, 2, 3]\) by Corrigan-Sasaki \([4]\). Similar phenomena are also reported by Ragnisco-Sasaki \([5]\) for Ruijsenaars-Schneider systems \([6, 7, 8, 9]\), which are deformation of C-M systems.

In this paper we will discuss one special aspect of the classical equilibria of exactly solvable systems based on classical root systems, the rational and trigonometric Ruijsenaars-Schneider systems. Namely, the determination of the equilibrium positions and their description in terms of certain polynomials. It is known that for the Calogero and Sutherland systems, the equilibrium positions are described by the zeros of the classical orthogonal polynomials, \(ie\) the Hermite, Laguerre, Chebyshev, Legendre, Gegenbauer and Jacobi polynomials \([4, 10, 11]\). The Ruijsenaars-Schneider systems are ‘good’ deformation of the Calogero and Sutherland systems. Here is one interesting evidence. It was known \([12]\) that the singular vectors of the Virasoro and \(W_N\) algebras, in the free field representation, are related to Jack polynomials \([13]\), the quantum eigenfunctions of the A type Sutherland systems. The deformed Virasoro and \(W_N\) algebras were discovered by using the relation between the Sutherland system and the trigonometric Ruijsenaars-Schneider system of the A type root system \([14]\). Therefore it is expected that equilibrium positions of the rational and trigonometric Ruijsenaars-Schneider systems would give certain ‘good’ deformation of the classical orthogonal polynomials:

\[
\begin{array}{ccc}
\text{Calogero-Sutherland} & \rightarrow & \text{classical orthogonal polynomials} \\
\downarrow \text{‘good’ deformation} & & \downarrow \text{‘good’ deformation} \\
\text{Ruijsenaars-Schneider} & \rightarrow & \text{deformed classical orthogonal polynomials} \\
\downarrow \text{equilibrium positions} & & \\
\text{systems} & & \\
\end{array}
\]

In Ragnisco-Sasaki paper \([5]\), based on numerical analysis, the explicit forms of the lower degree members of the one-parameter deformation of the Hermite and Laguerre polynomials were presented. The present authors continued the numerical analysis and obtained the explicit forms of the lower degree members of the one and/or two-parameter deformation of the Hermite polynomial, one, two and/or three-parameter deformation of the Laguerre polynomial, one-parameter deformation of the Jacobi (and Gegenbauer and Legendre) polynomials. They are also polynomials, or rational functions in the deformation parameter(s)
Remarkably the orthogonality of the original polynomials is inherited by the deformed ones. The equations determining the equilibrium can be reformulated as functional equations determining the polynomials. These functional equations are difference analogs of the celebrated second order differential equations satisfied by the classical orthogonal polynomials. Three term recurrence for the deformed polynomials, the necessary and sufficient condition for orthogonality, can be derived from these functional equations. Dynamical stability of the Hamiltonian system, or bounded-from-belowness of its potentials, is achieved by restricting the parameter space of the coupling constants, usually by positive coupling constants, which in turn guarantees the positive definiteness of the inner product governing the orthogonal polynomials, the deformed as well as undeformed. These deformed polynomials are not the so-called $q$-deformed versions of the above classical polynomials [13].

This paper is organized as follows. In section 2, first we recall the essence of the Calogero-Sutherland systems and their equilibria, which are described by the Hermite, Laguerre and Jacobi polynomials. Next the Hamiltonians and potentials of the Ruijsenaars-Schneider (R-S) systems are briefly recapitulated, and two types of the rational systems and one trigonometric systems for the classical root systems are introduced. Then the equations for their equilibrium positions are written down. For later use we review the relation between the orthogonal polynomials and the three-term recurrence. Section 3, 4 and 5 give the main results of this paper. In section 3 we determine the equilibrium positions of the rational R-S systems for the $A$ type root system and the deformation of the Hermite polynomial is presented. For one parameter deformation case, we derive the explicit forms of the generating function and the weight function of the inner product. In section 4 equilibrium positions of the rational R-S systems for $B, C, D, BC$ type root system are determined and the deformation of the Laguerre polynomial is presented together with the explicit forms of the functional equations and three-term recurrence. In section 5 equilibrium positions of the trigonometric R-S systems for the $B, C, D, BC$ type root system are determined and the deformation of the Jacobi (and Gegenbauer) polynomial is presented together with the explicit forms of the functional equations and three-term recurrence. Classical orthogonal polynomials, eg, the Hermite and Laguerre, satisfy many interesting identities among themselves. Those having a root theoretic explanation (folding) are shown to be preserved after deformation. Final section is devoted to summary and comments. Identification of the deformed orthogonal polyno-
mials within the so-called Askey-scheme of hypergeometric orthogonal polynomials [10] is reported here. The relation between the functional equation and the three-term recurrence is discussed in the Appendix.

2 Potentials and Equilibrium Positions

In this section we set up models and present the equations for their equilibrium positions. We consider a multi-particle classical mechanics governed by a classical Hamiltonian \( H(p, q) \). The dynamical variables are the coordinates \( \{q_j| j = 1, \ldots, r\} \) and their canonically conjugate momenta \( \{p_j| j = 1, \ldots, r\} \). These will be denoted by vectors in \( \mathbb{R}^r \)

\[
q = (q_1, \ldots, q_r), \quad p = (p_1, \ldots, p_r),
\]

in which \( r \) is the number of particles (and it is also the rank of the underlying root system \( \Delta \) except for the \( A \) case). The canonical equations of motion are

\[
\dot{q}_j = \frac{\partial H(p, q)}{\partial p_j}, \quad \dot{p}_j = -\frac{\partial H(p, q)}{\partial q_j}.
\]  (2.1)

The equilibrium positions are the stationary solution

\[
p = 0, \quad q = \bar{q},
\]  (2.2)

in which \( \bar{q} \) satisfies

\[
\frac{\partial H(0, q)}{\partial q_j} \bigg|_{q = \bar{q}} = 0, \quad (j = 1, \ldots, r).
\]  (2.3)

We will discuss Ruijsenaars-type models associated with the classical root systems, namely the \( A_{r-1} \), \( B_r \), \( C_r \), \( D_r \) and \( BC_r \). The fact that all the roots of the classical root systems are neatly expressed in terms of the orthonormal basis of \( \mathbb{R}^r \) makes formulation much simpler than those systems based on the exceptional root systems. The sets of positive roots of the classical root systems are

\[
A_{r-1} : \Delta_+ = \{e_j - e_k| 1 \leq j < k \leq r\},
\]
\[
B_r : \Delta_{L+} = \{e_j \pm e_k| 1 \leq j < k \leq r\}, \quad \Delta_{S+} = \{e_j| 1 \leq j \leq r\},
\]
\[
C_r : \Delta_{S+} = \{e_j \pm e_k| 1 \leq j < k \leq r\}, \quad \Delta_{L+} = \{2e_j| 1 \leq j \leq r\},
\]
\[
D_r : \Delta_+ = \{e_j \pm e_k| 1 \leq j < k \leq r\},
\]
\[
BC_r : \Delta_{M+} = \{e_j \pm e_k| 1 \leq j < k \leq r\},
\]
\[
\Delta_{S+} = \{e_j| 1 \leq j \leq r\}, \quad \Delta_{L+} = \{2e_j| 1 \leq j \leq r\},
\]
where \( \{e_j\} \) is an orthonormal basis of \( \mathbb{R}^r \). The subscripts \( L, M \) and \( S \) stand for long, middle and short roots, respectively.

It is well known that the non-simply laced root systems are obtained from simply laced ones by folding. In the present case, the relevant ones are:

\[
A_{2r-1} \rightarrow C_r, \quad D_{r+1} \rightarrow B_r, \quad A_{2r} \rightarrow BC_r.
\]

(2.4)

At the level of the dynamical variables and Hamiltonians, the above foldings are realised as:

\[
A_{2r-1} \rightarrow C_r : \quad p_{2r+1-j} = -p_j, \quad q_{2r+1-j} = -q_j, \quad (j = 1, \ldots, r), \quad (2.5)
\]

\[
D_{r+1} \rightarrow B_r : \quad p_{r+1} = q_{r+1} = 0, \quad (2.6)
\]

\[
A_{2r} \rightarrow BC_r : \quad p_{2r+2-j} = -p_j, \quad q_{2r+2-j} = -q_j, \quad (j = 1, \ldots, r), \quad p_{r+1} = q_{r+1} = 0. \quad (2.7)
\]

### 2.1 Calogero and Sutherland Systems

For later comparison, we summarise the Calogero and Sutherland systems associated with the classical root systems only, namely the \( A_{r-1}, B_r, C_r, D_r \) and \( BC_r \).

The Hamiltonian of the classical Calogero and Sutherland systems is

\[
H_{CS}(p, q) = \frac{1}{2} \sum_{j=1}^{r} p_j^2 + V_C(q),
\]

(2.8)

where the classical potential \( V_C \) is given below explicitly. For all cases this classical potential \( V_C \) can be written in terms of the prepotential \( W(q) \) [17]

\[
V_C(q) = \frac{1}{2} \sum_{j=1}^{r} \left( \frac{\partial W(q)}{\partial q_j} \right)^2.
\]

(2.9)

The equations for the equilibrium positions (2.3) reduce to the following equations:

\[
\frac{\partial W(q)}{\partial q_j} \bigg|_{q=\bar{q}} = 0, \quad (j = 1, \ldots, r).
\]

(2.10)

#### 2.1.1 Calogero Systems

The classical potential \( V_C \) and prepotential \( W \) are

\[
V_C(q) = \frac{\omega^2}{2} \sum_{j=1}^{r} q_j^2 + \frac{1}{2} \sum_{\rho \in \Delta_+} g_{\rho}^2 \rho^2 (\rho \cdot q)^2,
\]

(2.11)

\[
W(q) = -\frac{\omega}{2} \sum_{j=1}^{r} q_j^2 + \sum_{\rho \in \Delta_+} g_{\rho} \log |(\rho \cdot q)|,
\]

(2.12)
where $\omega$ is the (positive) frequency of the harmonic confining potential and $g_\rho$ are real positive coupling constants depending on the length of the roots. They are: one coupling $g$ for all roots for the $A_{r-1}$ and $D_r$, two independent couplings $g_L$ and $g_S$ for $B_r$ and $C_r$ corresponding to the long and short roots, respectively. These conventions are the same for all other types of potentials considered in this paper. For example, the $C_r$ model is

$$C_r : V_C(q) = \frac{\omega^2}{2} \sum_{j=1}^{r} q_j^2 + \frac{g_S^2}{2} \sum_{j,k=1 \atop j \neq k}^{r} \left( \frac{1}{(q_j - q_k)^2} + \frac{1}{(q_j + q_k)^2} \right) + \frac{g_L^2}{2} \sum_{j=1}^{r} \frac{1}{q_j^2},$$

$$W(q) = -\frac{\omega}{2} \sum_{j=1}^{r} q_j^2 + \frac{g_S}{2} \sum_{j,k=1 \atop j \neq k}^{r} \log |q_j^2 - q_k^2| + g_L \sum_{j=1}^{r} \log |2q_j|.$$

There is no distinction between the rational $B_r$ and $C_r$ models because of the replacement $g_S \leftrightarrow g_L$. The $D_r$ model can be considered as a special case of the $B_r$ with $g_L = g$ and $g_S = 0$.

The systems obtained by folding (2.5)–(2.7) have a special ratio of couplings. They are

folded $C_r : (g_L,g_S) = \left( \frac{1}{2},1 \right)$,
folded $B_r : (g_L,g_S) = (1,2)$,
folded $BC_r : (g_L,g_M,g_S) = \left( \frac{1}{2},1,1 \right)$.

The equations for the equilibrium position (2.10) are

$$A_{r-1} : \sum_{k=1 \atop k \neq j}^{r} \frac{1}{q_j - q_k} = \frac{\omega}{g} \bar{q}_j,$$

$$B_r : \sum_{k=1 \atop k \neq j}^{r} \frac{2\bar{q}_j}{q_j^2 - q_k^2} = \frac{\omega}{g_L} \bar{q}_j - \frac{g_S}{g_L} \frac{1}{\bar{q}_j},$$

$$C_r : \sum_{k=1 \atop k \neq j}^{r} \frac{2\bar{q}_j}{q_j^2 - q_k^2} = \frac{\omega}{g_S} \bar{q}_j - \frac{g_L}{g_S} \frac{1}{\bar{q}_j},$$

$$D_r : \sum_{k=1 \atop k \neq j}^{r} \frac{2\bar{q}_j}{q_j^2 - q_k^2} = \frac{\omega}{g} \bar{q}_j.$$

They determine the zeros of the Hermite and Laguerre polynomials. In other words, if we define $\bar{q}_j = \sqrt{\frac{2^r}{\omega}} y_j$ for $A_{r-1}$, then the polynomial having $\{y_j\}$ as zeros is the Hermite polynomial [10] [18] [4]:

$$2^r \prod_{j=1}^{r} (x - y_j) = r! \sum_{j=0}^{[\frac{r}{2}]} (-1)^j (2x)^{r-2j} \frac{d^j}{dx^j} H_r(x).$$

(2.18)
For the \( C_r \) (or \( B_r \)) model let us define \( \bar{q}_j = \sqrt{\frac{\omega}{g}} y_j \), \( \alpha = \frac{g_S}{g_S} - 1 \) then having \( \{ y_j^2 \} \) as zeros is the Laguerre polynomial [10, 18, 4]:

\[
\frac{(-1)^r}{r!} \prod_{j=1}^{r} (x - y_j^2) = \sum_{j=0}^{r} \frac{(r + \alpha)}{r - j} \frac{(-x)^j}{r!} \stackrel{\text{def}}{=} L_r^{(\alpha)}(x). \tag{2.19}
\]

For the \( D_r \) root system, it is the Laguerre polynomial \( L_r^{(-1)}(x) \).

The identities between the Hermite and Laguerre polynomials

\[
2^{-2r} H_{2r}(x) = (-1)^r r! L_r^{(-\frac{1}{2})}(x^2), \tag{2.20}
\]

\[
2^{-2r-1} H_{2r+1}(x) = x (-1)^r r! L_r^{(\frac{1}{2})}(x^2), \tag{2.21}
\]

are well-known. The former identity (2.20) for the even degree Hermite polynomial can be understood as a consequence of the folding of the root system \( A_{2r-1} \to C_r \), see (2.5). Likewise the latter identity (2.21) for the odd degree Hermite polynomial can be understood as a consequence of the folding of the root system \( A_{2r} \to B C_r \), see (2.7). Next let us consider the folding \( D_{r+1} \to B_r \) (2.6), which leads to the identity [4] among the Laguerre polynomials of different indices:

\[
(r + 1) L_{r+1}^{(-1)}(x) = -x L_r^{(1)}(x). \tag{2.22}
\]

We will see that these identities (2.20), (2.21) and (2.22) are also nicely deformed with one parameter (4.46), (4.48) and (4.50) and with two parameters (4.47), (4.49) and (4.51).

### 2.1.2 Sutherland Systems

The classical potential \( V_C \) and prepotential \( W \) are (except for \( V_C \) of \( B C_r \))

\[
V_C(q) = \frac{1}{2} \sum_{\rho \in \Delta^+} \frac{g^2 \rho^2}{\sin^2(\rho \cdot q)}, \tag{2.23}
\]

\[
W(q) = \sum_{\rho \in \Delta^+} g_\rho \log |\sin(\rho \cdot q)|, \tag{2.24}
\]

where \( g_\rho \) are real positive coupling constants. The classical potential \( V_C \) of the \( B C_r \) model is given by

\[
\begin{align*}
BC_r : V_C(q) &= \frac{g_M^2}{2} \sum_{j,k=1}^{r} \left( \frac{1}{\sin^2(q_j - q_k)} + \frac{1}{\sin^2(q_j + q_k)} \right) \\
&\quad + 2g_l^2 \sum_{j=1}^{r} \frac{1}{\sin^2 2q_j} + g_S(g_S + 2g_L) \sum_{j=1}^{r} \frac{1}{\sin^2 q_j}. \tag{2.25}
\end{align*}
\]
The $B_r$ ($C_r$) potential is obtained by setting $g_L = 0, g_M \to g_L, (g_S = 0, g_M \to g_S)$.

The equations for the equilibrium position (2.10) are

$$A_{r-1} : \sum_{k=1}^{r} \cot(\bar{q}_j - \bar{q}_k) = 0,$$  \hfill (2.26)

$$B_r : \sum_{k=1, k\neq j}^{r} \left( \cot(\bar{q}_j - \bar{q}_k) + \cot(\bar{q}_j + \bar{q}_k) \right) = -\frac{g_S}{g_L} \cot \bar{q}_j,$$  \hfill (2.27)

$$C_r : \sum_{k=1, k\neq j}^{r} \left( \cot(\bar{q}_j - \bar{q}_k) + \cot(\bar{q}_j + \bar{q}_k) \right) = -2\frac{g_L}{g_S} \cot 2\bar{q}_j,$$  \hfill (2.28)

$$BC_r : \sum_{k=1, k\neq j}^{r} \left( \cot(\bar{q}_j - \bar{q}_k) + \cot(\bar{q}_j + \bar{q}_k) \right) = -\frac{g_s}{g_M} \cot \bar{q}_j - 2\frac{g_L}{g_M} \cot 2\bar{q}_j,$$  \hfill (2.29)

$$D_r : \sum_{k=1, k\neq j}^{r} \left( \cot(\bar{q}_j - \bar{q}_k) + \cot(\bar{q}_j + \bar{q}_k) \right) = 0.$$  \hfill (2.30)

The equilibrium positions of the $A_{r-1}$ model are related to the Chebyshev polynomial and those of the other models are related to the Jacobi polynomials.

For the $A_{r-1}$, the equilibrium positions are "equally-spaced" and translational invariant,

$$\bar{q} = \frac{\pi}{r} \left( r(r-1), \cdots, 1 \right) + \xi \left( 1, 1, \cdots, 1 \right), \quad \xi \in \mathbb{R} : \text{arbitrary}.$$  \hfill (2.31)

We choose this constant shift $\xi$ such that the "center of mass" coordinate vanishes, $\sum_{j=1}^{r} \bar{q}_j = 0$:

$$\bar{q}_j = \frac{\pi(r+1-j)}{r} - \frac{\pi(r+1)}{2r} = \frac{\pi}{2} - \frac{\pi(2j-1)}{2r} = -\bar{q}_{r+1-j}, \quad (j = 1, \ldots, r).$$  \hfill (2.32)

Then the degree $r$ (the dimension of the vector representation) polynomial in $x$, having zeros at $\{\sin \bar{q}_j\}$,

$$2^{r-1} \prod_{j=1}^{r} (x - \sin \bar{q}_j) = 2^{r-1} \prod_{j=1}^{r} \left( x - \cos \frac{\pi(2j-1)}{2r} \right) \overset{\text{def}}{=} T_r(x),$$  \hfill (2.33)

is the Chebyshev polynomial of the first kind, $T_n(\cos \varphi) = \cos(n \varphi)$.

For the solution $\{\bar{q}_j\}$ of the $BC_r$ (2.29), $\cos 2\bar{q}_j$ is the zero of the Jacobi polynomial $P_r^{(\alpha,\beta)}(x)$ with $\alpha = \frac{g_S}{g_M} + \frac{g_L}{g_M} - 1$ and $\beta = \frac{g_L}{g_M} - 1$,

$$2^{-r} (\alpha + \beta + 2r) \prod_{j=1}^{r} (x - \cos 2\bar{q}_j) = \sum_{j=0}^{r} \binom{\alpha + r}{\alpha + \beta + 1} j \frac{(x - 1)^j}{2^j} \overset{\text{def}}{=} P_r^{(\alpha,\beta)}(x).$$  \hfill (2.34)
It is easily shown that $\bar{q}_j = \frac{π}{2} - \bar{q}_j$ satisfies (2.29) with $\alpha \leftrightarrow \beta$, which implies $P_n^{(α,β)}(−x) = (−1)^n P_n^{(β,α)}(x)$. For the solution $\{\bar{q}_j\}$ of the $C_r$ (2.28), $cos 2\bar{q}_j$ is the zero of the Gegenbauer polynomial $C_r^{(α+\frac{1}{2})}(x)$ with $α = \frac{g_κ}{g_β} - 1$,

$$2^r (α−\frac{1}{2} + r) \prod_{j=1}^r (x − cos 2\bar{q}_j) = (\frac{2α+r}{r}) (\frac{α+r}{r})^{-1} \sum_{j=0}^r (α+r) (α+β+r+j) 2^{-j} (x−1)^j \overset{def}{=} C_r^{(α+\frac{1}{2})}(x).$$

This is a special case of $P_r^{(α,β)}(x)$ with another normalisation,

$$C_r^{(α+\frac{1}{2})}(x) = (\frac{2α+r}{r}) (\frac{α+r}{r})^{-1} P_r^{(α,α)}(x).$$

For the solution $\{\tilde{q}_j\}$ of the $B_r$ (2.27), $cos 2\tilde{q}_j$ is the zero of $P_r^{(α,−1)}(x)$ with $α = \frac{g_κ}{g_β} - 1$. For the solution $\{\tilde{q}_j\}$ of the $D_r$ (2.30), $cos 2\tilde{q}_j$ is the zero of $P_r^{(−1,−1)}(x)$.

The known identities between the Chebyshev and Jacobi polynomials and between the Gegenbauer polynomial and the Jacobi polynomial are also related by the quadratic transformations:

$$A_{2r−1} \rightarrow C_r : 2^{1−2r} T_{2r}(x) = (−1)^r (\frac{2r−1}{r})^{-1} P_r^{(−\frac{1}{2},−\frac{1}{2})}(1−2x^2),$$

$$A_{2r} \rightarrow BC_r : 2^{−2r} T_{2r+1}(x) = x (−1)^r (\frac{2r}{r})^{-1} P_r^{(\frac{1}{2},−\frac{1}{2})}(1−2x^2),$$

$$D_{r+1} \rightarrow B_r : 2(r+1) P_{r+1}^{(−1,−1)}(x) = r(x−1) P_r^{(1,−1)}(x).$$

We will see in the following that the first two identities are not deformed but the third one is nicely deformed (5.53).

The Gegenbauer polynomial and the Jacobi polynomial are also related by the quadratic transformations:

$$C_{2n}^{(α+\frac{1}{2})}(x) = 2^{2n} (\frac{α−\frac{1}{2}+n}{n}) (\frac{2n}{n})^{-1} P_n^{(α−\frac{1}{2})}(2x^2−1),$$

$$C_{2n+1}^{(α+\frac{1}{2})}(x) = 2^{2n+1} (\frac{α+\frac{1}{2}+n+1}{n+1}) (\frac{2n+1}{n+1})^{-1} x P_n^{(α,\frac{1}{2})}(2x^2−1).$$

However these identities do not seem to have a folding type explanation. Indeed the deformed Gegenbauer polynomials $C_n^{(α+\frac{1}{2})}(x, δ)$ (5.13), $C_n^{(α+\frac{1}{2})}(x, δ)$ (5.20) and the deformed Jacobi polynomial $P_n^{(α,β)}(x, δ)$ (5.2) do not satisfy this type of identities for generic $δ$.

### 2.2 Ruijsenaars-type Systems

Following Ruijsenaars-Schneider [6] and van Diejen [7], the Hamiltonian of the Ruijsenaars systems is (the deformation parameter $β'$ of $e^{±βp}$ is set to unity, $β' = 1$)

$$H(p, q) = \sum_{j=1}^r \left( \cosh p_j \sqrt{V_j(q) V_j^*(q)} - \frac{1}{2} \left( \frac{V_j(q) + V_j^*(q)}{2} \right) \right).$$

(2.42)
The form of the function $V_j = V_j(q)$ and its complex conjugate $V_j^*$ are determined by the root system $\Delta$ as:

$$A_{r-1} : \quad V_j(q) = w(q_j) \prod_{k=1 \atop k \neq j}^r v(q_j - q_k), \quad (j = 1, \ldots, r), \quad (2.43)$$

$$B_r, C_r, D_r, BC_r : \quad V_j(q) = w(q_j) \prod_{k=1 \atop k \neq j}^r v(q_j - q_k) v(q_j + q_k), \quad (j = 1, \ldots, r). \quad (2.44)$$

The elementary potential functions $v$ and $w$ depend on the nature of interactions (rational, trigonometric, etc) and the root system $\Delta$. Their explicit forms will be given below. When $V$ satisfies the simple identity $\sum_j \left( V_j(q) + V_j^*(q) \right) = \text{const.}$, the Hamiltonian (2.42) could be replaced by a simpler one

$$H'(p, q) = \sum_{j=1}^r \cosh p_j \sqrt{V_j(q) V_j^*(q)}, \quad (2.45)$$

which is obviously positive definite and usually used as a starting point for the trigonometric (hyperbolic) interaction theory.

The above Hamiltonian (2.42) is a hyperbolic function of the momentum operator $p$ instead of a polynomial in the hierarchy of C-M systems or other ordinary dynamical systems. In quantum theoretical setting this Hamiltonian causes finite shifts of the wavefunction in the imaginary direction, i.e. $\cosh p \psi(q) = \frac{1}{2}(\psi(q - i\hbar) + \psi(q + i\hbar))$, in which $\hbar$ is Planck’s constant. This is why the R-S systems are sometimes called ‘discrete’ dynamical systems.

The equation (2.3) of equilibrium positions (2.2) can be simplified in the following way. By expanding the Hamiltonian around the stationary solution (2.2), we obtain

$$H(p, q) = K(p) + P(q) + \text{higher order terms in } p, \quad K(p) = \frac{1}{2} \sum_{j=1}^r |V_j(q)| p_j^2, \quad (2.46)$$

and the ‘potential’ $P$ is given by

$$P(q) = \sum_{j=1}^r \left( \sqrt{V_j(q) V_j^*(q)} - \frac{1}{2} \left( V_j(q) + V_j^*(q) \right) \right) = -\frac{1}{2} \sum_{j=1}^r \left( \sqrt{V_j(q)} - \sqrt{V_j^*(q)} \right)^2. \quad (2.47)$$

This should be compared with the classical potential in the Calogero-Sutherland systems (2.9). It is obvious that the equilibrium is achieved at the point(s) in which all the functions $V_j$ become real and positive:

$$V_j(q) = V_j^*(q) > 0, \quad (j = 1, 2, \ldots, r). \quad (2.48)$$
The equilibrium point is the absolute minimum of the potential $P$. The system of equations (2.48) is invariant under any permutation of $\{\bar{q}_j\}$. For $v$ and $w$ considered in this paper, they are also invariant under the transformation $q \rightarrow q' = -q$. Except for the $A$ case, they are also invariant under the transformation $q \rightarrow q' = t(\epsilon_1 q_1, \cdots, \epsilon_r q_r)$ with $\epsilon_i = \pm 1$.

The functions $v$ and $w$ considered in this paper have properties

$$v(-x) = v^*(x), \quad w(-x) = w^*(x), \quad (2.49)$$

which allow the folding (2.50)–(2.53) of the Ruijsenaars type Hamiltonians:

$$H^{A_{2r-1}}(p, q) \bigg|_{p_{2r+1-j} = -p_j, \; q_{2r+1-j} = -q_j} = 2\tilde{H}(p, q), \quad \tilde{v}(x) = v^A(x), \quad \tilde{w}(x) = w^A(x)v^A(2x), \quad (2.50)$$

$$H^{A_{2r}}(p, q) \bigg|_{p_{2r+2-j} = -p_j, \; q_{2r+2-j} = -q_j} = 2\tilde{H}(p, q), \quad \tilde{v}(x) = v^A(x), \quad \tilde{w}(x) = w^A(x) v^A(x) v^A(2x), \quad (2.51)$$

$$H^{D_{r+1}}(p, q) \bigg|_{p_{r+1} = 0, q_{r+1} = 0} = \tilde{H}(p, q), \quad \tilde{v}(x) = v^D(x), \quad \tilde{w}(x) = w^D(x) v^D(x)^2, \quad (2.52)$$

where $\tilde{H}$ is

$$\tilde{H}(p, q) = \sum_{j=1}^r \left( \cosh p_j \sqrt{\tilde{V}_j(q)} \tilde{V}_j^*(q) - \frac{1}{2} \left( \tilde{V}_j(q) + \tilde{V}_j^*(q) \right) \right),$$

$$\tilde{V}_j(q) = \tilde{w}(q_j) \prod_{k=1}^r \tilde{v}(q_j - q_k) \tilde{v}(q_j + q_k). \quad (2.53)$$

The folded systems (2.50), (2.51) and (2.52) correspond to the folding $A_{2r-1} \rightarrow C_r$, $A_{2r} \rightarrow BC_r$ and $D_{r+1} \rightarrow B_r$, respectively. The coupling constants in these folded systems are not independent as shown in (2.13).

### 2.2.1 Ruijsenaars-Calogero Systems

The first example to be discussed is the ‘discrete’ analogue of the Calogero systems [1], to be called the Ruijsenaars-Calogero systems, which were introduced by van Diejen for the classical root systems only [7, 8]. The original Calogero systems [1] have the rational $(1/(\text{distance})^2)$ potential plus the harmonic confining potential, having two coupling constants $g$ and $\omega$ for the systems based on the simply-laced root systems, $A$ and $D$, and three couplings $\omega$ and $g_L$ for the long roots and $g_S$ for the short roots in the $B$ and $C$ root systems.

Two varieties (deformation) of ‘discrete’ Calogero systems are known. The first has two (three for the non-simply-laced root systems) coupling constants $g$ ($g_L$ and $g_S$) and $a$ which
corresponds to $\omega$ in the Calogero systems. The second has three (four for the non-simply-laced root systems) coupling constants $g$ ($g_L$ and $g_S$) and $a, b$ both of which correspond to $\omega$. The integrability (classical and quantum) of these systems was discussed by van Diejen in some detail \[7, 8\]. The former can be considered as a limiting case ($b \to \infty$) of the latter.

Linear Confining Potential Case

The dynamical system is defined by giving the explicit forms of the elementary potential functions $v$ and $w$. For the simply-laced root systems $A$ and $D$ they are:

$$A, D : v(x) = 1 - i \frac{g}{x}, \quad w(x) = 1 + i \frac{x}{a},$$

(2.54)

in which $a$ and $g$ are real positive coupling constants. For the non-simply-laced root systems $B, C$ and $\sim BC$, we have:

$$B : v(x) = 1 - i \frac{g_L}{x}, \quad w(x) = \left(1 + i \frac{x}{a}ight)\left(1 - i \frac{g_S}{2x}\right),$$

(2.55)

$$C : v(x) = 1 - i \frac{g_S}{x}, \quad w(x) = \left(1 + i \frac{x}{a}\right)\left(1 - i \frac{g_L}{x}\right),$$

(2.56)

$$\sim BC : v(x) = 1 - i \frac{g_0}{x}, \quad w(x) = \left(1 + i \frac{x}{a}\right)\left(1 - i \frac{g_1}{x}\right)\left(1 - i \frac{g_2}{x}\right),$$

(2.57)

in which $a, g_L, g_S, g_0, g_1, g_2$ are independent real positive coupling constants. Normalisation of the coupling constants is chosen such that they reduce to those of the Calogero models in the small coupling limits discussed below. The $D$ model is obtained from the $B$ model by $g_L = g$ and $g_S = 0$. The $B$ and $C$ models are special cases of the $\sim BC$ model. In contrast to the Calogero case, those based on the $B$ and $C$ systems are different. The difference of the length of the roots is immaterial, since it can be absorbed by the coupling constants normalisation. It is rather elementary to derive the forms of the Hamiltonians of the $B$ and $C$ systems from those of the $D$ and $A$ systems by folding (see (2.52) and (2.50)). In all these cases the ‘potential’ $P$ (2.47) grows linearly in $|q|$ as $|q| \to \infty$. Except for the $\sim BC$ case, there are simple identities: $\sum_j (V_j(q) + V_j^*(q)) = \text{const.}$

In the limit of small coupling constants, namely, by recovering the deformation parameter $\beta'$,

$$\left(p_j, \frac{1}{a}, g, g_L, g_S, g_0, g_1, g_2\right) \to \beta' \left(p_j, \frac{1}{a}, g, g_L, g_S, g_0, g_1, g_2\right),$$

(2.58)

and taking $\beta' \to 0$ limit, the Hamiltonian (2.42) tends to that of the corresponding classical Calogero system \[28\] with $\omega = \frac{1}{a}$ ($\sim BC$ tends to $C$ with $g_S = g_0$, $g_L = g_1 + g_2$)

$$\frac{1}{\beta'2} H(p, q) \to H_{\text{Calogero}}(p, q) + \text{const.}$$

(2.59)
It is interesting to note that the equations determining the equilibrium (2.48), in general, can be cast in a form which looks similar to the Bethe ansatz equation. For the elementary potential (2.54)–(2.57), the equilibrium positions \{\tilde{q}_j\} are determined by:

\[ A_{r-1} : \prod_{k=1 \atop k \neq j}^r \frac{\tilde{q}_j - \tilde{q}_k - ig}{\tilde{q}_j - \tilde{q}_k + ig} = \frac{a - i\tilde{q}_j}{a + i\tilde{q}_j}, \quad (2.60) \]

\[ B_r : \prod_{k=1 \atop k \neq j}^r \frac{\tilde{q}_j - \tilde{q}_k - i g_L}{\tilde{q}_j - \tilde{q}_k + i g_L} \frac{\tilde{q}_j + \tilde{q}_k - ig_L}{\tilde{q}_j + \tilde{q}_k + ig_L} = \frac{a - i\tilde{q}_j}{a + i\tilde{q}_j} \left( \frac{2\tilde{q}_j + ig_S}{2\tilde{q}_j - ig_S} \right)^2, \quad (2.61) \]

\[ C_r : \prod_{k=1 \atop k \neq j}^r \frac{\tilde{q}_j - \tilde{q}_k - i g_S}{\tilde{q}_j - \tilde{q}_k + i g_S} \frac{\tilde{q}_j + \tilde{q}_k - ig_S}{\tilde{q}_j + \tilde{q}_k + ig_S} = \frac{a - i\tilde{q}_j}{a + i\tilde{q}_j} \frac{\tilde{q}_j + ig_L}{\tilde{q}_j - ig_L}, \quad (2.62) \]

\[ \widetilde{BC}_r : \prod_{k=1 \atop k \neq j}^r \frac{\tilde{q}_j - \tilde{q}_k - ig_0}{\tilde{q}_j - \tilde{q}_k + ig_0} \frac{\tilde{q}_j + \tilde{q}_k - ig_0}{\tilde{q}_j + \tilde{q}_k + ig_0} = \frac{a - i\tilde{q}_j}{a + i\tilde{q}_j} \frac{\tilde{q}_j + ig_1}{\tilde{q}_j - ig_1} \frac{\tilde{q}_j + ig_2}{\tilde{q}_j - ig_2}, \quad (2.63) \]

\[ D_r : \prod_{k=1 \atop k \neq j}^r \frac{\tilde{q}_j - \tilde{q}_k - ig}{\tilde{q}_j - \tilde{q}_k + ig} = \frac{a - i\tilde{q}_j}{a + i\tilde{q}_j}. \quad (2.64) \]

In the above small coupling limits, these equations reduce to (2.61)–(2.64). Thus the Bethe ansatz-like equations (2.60)–(2.64) would give deformation of the Hermite and Laguerre polynomials, as we will see in section 3.1 and 4.1. They are not the so-called \(q\)-deformed Hermite or Laguerre polynomials [15].

**Quadratic Confining Potential Case**

In this case the elementary potential function \(v\) is the same as before, but \(w\) is different. For the simply-laced root systems \(A\) and \(D\), the elementary potential functions are:

\[ A, D : \quad v(x) = 1 - i \frac{g}{x}, \quad w(x) = \left(1 + i \frac{x}{a}\right)\left(1 + i \frac{x}{b}\right), \quad (a, b, g > 0). \quad (2.65) \]

For the non-simply-laced root systems \(B, C\) and \(\widetilde{BC}\), we have (\(g_L, g_S, g_0, g_1, g_2 > 0\)):

\[ B : \quad v(x) = 1 - i \frac{g_L}{x}, \quad w(x) = \left(1 + i \frac{x}{a}\right) \left(1 + i \frac{x}{b}\right) \left(1 - i \frac{g_S}{2x}\right)^2, \quad (2.66) \]

\[ C : \quad v(x) = 1 - i \frac{g_S}{x}, \quad w(x) = \left(1 + i \frac{x}{a}\right) \left(1 + i \frac{x}{b}\right) \left(1 - i \frac{g_L}{x}\right), \quad (2.67) \]

\[ \widetilde{BC} : \quad v(x) = 1 - i \frac{g_0}{x}, \quad w(x) = \left(1 + i \frac{x}{a}\right) \left(1 + i \frac{x}{b}\right) \left(1 - i \frac{g_1}{x}\right) \left(1 - i \frac{g_2}{x}\right). \quad (2.68) \]

The \(D\) model can be considered as a special case of the \(B\) model by \(g_L = g\) and \(g_S = 0\). The \(B\) and \(C\) models are special cases of \(\widetilde{BC}\) model. As in the previous case, the forms of
the elementary potential function \( w \) for \( B \) and \( C \) systems are determined from those of the \( D \) and \( A \) systems by folding (2.52), (2.50). In all these cases the ‘potential’ \( P \) (2.47) grows quadratically in \( |q| \) as \( |q| \to \infty \). The small coupling limit (2.58) (and \( \frac{1}{b} \to \frac{2}{b} \)) gives the same classical Calogero systems as before (2.59), (2.8) with \( \omega = \frac{1}{a} + \frac{1}{b} \).

The equations (2.48) determining the equilibrium positions \( \{ \tilde{q}_j \} \) for the elementary potential (2.65)–(2.68) are expressed in a form similar to the Bethe ansatz equation:

\[
A_{r-1} : \prod_{k=1 \atop k \neq j}^{r} \frac{\tilde{q}_j - \tilde{q}_k - ig}{\tilde{q}_j - \tilde{q}_k + ig} = \frac{a - i\tilde{q}_j b - i\tilde{q}_j}{a + i\tilde{q}_j b + i\tilde{q}_j},
\]

(2.69)

\[
B_r : \prod_{k=1 \atop k \neq j}^{r} \frac{\tilde{q}_j - \tilde{q}_k - igL}{\tilde{q}_j - \tilde{q}_k + igL} \frac{\tilde{q}_j + \tilde{q}_k - igL}{\tilde{q}_j + \tilde{q}_k + igL} = \frac{a - i\tilde{q}_j b - i\tilde{q}_j}{a + i\tilde{q}_j b + i\tilde{q}_j} \left( \frac{2\tilde{q}_j + igS}{2\tilde{q}_j - igS} \right)^2,
\]

(2.70)

\[
C_r : \prod_{k=1 \atop k \neq j}^{r} \frac{\tilde{q}_j - \tilde{q}_k - igS}{\tilde{q}_j - \tilde{q}_k + igS} \frac{\tilde{q}_j + \tilde{q}_k - igS}{\tilde{q}_j + \tilde{q}_k + igS} = \frac{a - i\tilde{q}_j b - i\tilde{q}_j}{a + i\tilde{q}_j b + i\tilde{q}_j} \frac{\tilde{q}_j + igL}{\tilde{q}_j - igL},
\]

(2.71)

\[
\tilde{B}C_r : \prod_{k=1 \atop k \neq j}^{r} \frac{\tilde{q}_j - \tilde{q}_k - ig0}{\tilde{q}_j - \tilde{q}_k + ig0} \frac{\tilde{q}_j + \tilde{q}_k - ig0}{\tilde{q}_j + \tilde{q}_k + ig0} = \frac{a - i\tilde{q}_j b - i\tilde{q}_j}{a + i\tilde{q}_j b + i\tilde{q}_j} \frac{\tilde{q}_j + ig1}{\tilde{q}_j - ig1} \frac{\tilde{q}_j + ig2}{\tilde{q}_j - ig2},
\]

(2.72)

\[
D_r : \prod_{k=1 \atop k \neq j}^{r} \frac{\tilde{q}_j - \tilde{q}_k - ig}{\tilde{q}_j - \tilde{q}_k + ig} \frac{\tilde{q}_j + \tilde{q}_k - ig}{\tilde{q}_j + \tilde{q}_k + ig} = \frac{a - i\tilde{q}_j b - i\tilde{q}_j}{a + i\tilde{q}_j b + i\tilde{q}_j}.
\]

(2.73)

They define another type of deformation of the Hermite and Laguerre polynomials, since the small coupling limit of the above Bethe ansatz-like equations gives the same equations as before (2.14), (2.17), determining the zeros of the Hermite and Laguerre polynomials, with \( \omega = \frac{1}{a} + \frac{1}{b} \). These will be discussed in sections 3.2 and 4.2.

### 2.2.2 Ruijsenaars-Sutherland Systems

The discrete analogue of the Sutherland systems [2], to be called the Ruijsenaars-Sutherland systems, was introduced originally by Ruijsenaars and Schneider [6] for the \( A \) type root system. The quantum eigenfunctions of the \( A \) type Ruijsenaars-Sutherland systems are called Macdonald polynomials [19], which are a one-parameter deformation \( (q\text{-deformation}) \) of the Jack polynomials [13]. Here we will discuss the Ruijsenaars-Sutherland systems for all the classical root systems, \( A, B, C, D \) and \( BC \) [8]. The structure of the functions \( \{ V_j(q) \} \), (2.43) and (2.44) are the same as in the Ruijsenaars-Calogero systems, but the elementary potential functions \( v \) and \( w \) are trigonometric instead of rational. Because of the identity
\[
\sum_{j=1}^{r} \{ V_j(q) + V_j^*(q) \} = \text{const.}
\]
the Hamiltonian (2.42) could be replaced by a simpler one (2.43).

The elementary potential functions \(v\) and \(w\) are:

\[
A, D : v(x) = 1 - i \tanh g \cot x, \quad w(x) = 1, \quad (2.74)
\]

\[
B : v(x) = 1 - i \tanh g_L \cot x, \quad w(x) = (1 - i \tanh \frac{g_S}{2} \cot x)^2, \quad (2.75)
\]

\[
B' : v(x) = 1 - i \tanh g_L \cot x, \quad w(x) = 1 - i \tanh g_S \cot x, \quad (2.76)
\]

\[
C : v(x) = 1 - i \tanh g_S \cot x, \quad w(x) = 1 - i \tanh 2g_L \cot 2x, \quad (2.77)
\]

\[
C' : v(x) = 1 - i \tanh g_S \cot x, \quad w(x) = (1 - i \tanh g_L \cot 2x)^2, \quad (2.78)
\]

\[
B'C' : v(x) = 1 - i \tanh g_M \cot x,
\]

\[
w(x) = (1 - i \tanh g_S \cot x)(1 - i \tanh 2g_L \cot 2x), \quad (2.79)
\]

with similar coupling constant notation as in the rational cases. Normalisation of the coupling constants is chosen such that they reduce to those of the Sutherland models in the small coupling limits discussed below. The \(D\) model is the special case of the \(B\) model by \(g_L = g\) and \(g_S = 0\). The \(B'\) and \(C\) models are special cases of the \(B'C\) model. As in the rational cases, the forms of the elementary potential function \(w\) for the \(B\) and \(C\) systems are determined from those of the \(D\) and \(A\) systems by folding (2.52), (2.50).

The original Sutherland models are obtained in the limit in which all the coupling constant(s) become infinitesimally small. By recovering the deformation parameter \(\beta'\),

\[
(p_j, g, g_L, g_M, g_S) \to \beta' (p_j, g, g_L, g_M, g_S), \quad (2.80)
\]

and taking \(\beta' \to 0\) limit, the Hamiltonian (2.42) tends to that of the corresponding classical Sutherland system (2.8)

\[
\frac{1}{\beta'p^2} H(p, q) \to H_{\text{Sutherland}}(p, q) + \text{const}. \quad (2.81)
\]

In ‘strong’ coupling limits, \(g, g_L, g_M, g_S \to +\infty\), the elementary potential functions \(v\) and \(w\) take simple forms:

\[
v(x) \to 1 - i \cot x, \quad w(x) \to 1, \quad 1 - i \cot x, \quad (1 - i \cot x)^2, \quad \text{etc.} \quad (2.82)
\]

The deformed polynomials take simple forms in this limit as we will see in section 5.
The equations (2.38) determining the equilibrium positions \( \{ \bar{q}_j \} \) for the elementary potential (2.74)--(2.79) are expressed in a form similar to the Bethe ansatz equation:

\[
A_{r-1} : \prod_{k=1 \atop k \neq j}^{r} \tan(\bar{q}_j - \bar{q}_k) - i \tanh g \tan(\bar{q}_j - \bar{q}_k) + i \tanh g = 1, \quad (2.83)
\]

\[
B_r : \prod_{k=1 \atop k \neq j}^{r} \tan(\bar{q}_j - \bar{q}_k) - i \tanh g_L \tan(\bar{q}_j + \bar{q}_k) - i \tanh g_L \tan(\bar{q}_j + \bar{q}_k) + i \tanh g_L = \left( \frac{\tan \bar{q}_j + i \tanh \frac{g_S}{2}}{\tan \bar{q}_j - i \tanh \frac{g_S}{2}} \right)^2, \quad (2.84)
\]

\[
B'_r : \prod_{k=1 \atop k \neq j}^{r} \tan(\bar{q}_j - \bar{q}_k) - i \tanh g_L \tan(\bar{q}_j + \bar{q}_k) - i \tanh g_L \tan(\bar{q}_j + \bar{q}_k) + i \tanh g_L = \tan \bar{q}_j + i \tanh g_S \tan \bar{q}_j - i \tanh g_S, \quad (2.85)
\]

\[
C_r : \prod_{k=1 \atop k \neq j}^{r} \tan(\bar{q}_j - \bar{q}_k) - i \tanh g_S \tan(\bar{q}_j + \bar{q}_k) - i \tanh g_S \tan(\bar{q}_j + \bar{q}_k) + i \tanh g_S = \tan 2\bar{q}_j + i \tanh 2g_L \tan 2\bar{q}_j - i \tanh 2g_L, \quad (2.86)
\]

\[
C'_r : \prod_{k=1 \atop k \neq j}^{r} \tan(\bar{q}_j - \bar{q}_k) - i \tanh g_S \tan(\bar{q}_j + \bar{q}_k) - i \tanh g_S \tan(\bar{q}_j + \bar{q}_k) + i \tanh g_S = \left( \frac{\tan 2\bar{q}_j + i \tanh g_L}{\tan 2\bar{q}_j - i \tanh g_L} \right)^2, \quad (2.87)
\]

\[
B'C_r : \prod_{k=1 \atop k \neq j}^{r} \tan(\bar{q}_j - \bar{q}_k) - i \tanh g_M \tan(\bar{q}_j + \bar{q}_k) - i \tanh g_M \tan(\bar{q}_j + \bar{q}_k) + i \tanh g_M = \tan \bar{q}_j + i \tanh g_S \tan 2\bar{q}_j + i \tanh 2g_L \tan 2\bar{q}_j - i \tanh 2g_L, \quad (2.88)
\]

\[
D_r : \prod_{k=1 \atop k \neq j}^{r} \tan(\bar{q}_j - \bar{q}_k) - i \tanh g \tan(\bar{q}_j + \bar{q}_k) - i \tanh g \tan(\bar{q}_j + \bar{q}_k) + i \tanh g = 1. \quad (2.89)
\]

From the property mentioned after (2.38) and the fact that (2.83)--(2.89) are the equations of \( \{ \tan \bar{q}_j \} \), we can restrict \( \bar{q}_j \) to \( 0 \leq \bar{q}_j \leq \pi/2 \) (except for the \( A_{r-1} \) case). In the small coupling limit, these equations (2.83)--(2.89) tend to (2.20)--(2.31). Thus the Bethe ansatz-like equations (2.83)--(2.89) would give deformation of the Chebyshev and Jacobi polynomials as we will see in section 5.

### 2.3 Orthogonal Polynomials and Three Term Recurrences

It is well known that orthogonal polynomials satisfy three-term recurrence [18, 20] and conversely a sequence of polynomials satisfying three-term recurrence are orthogonal with respect to certain inner product with some weight function. Here we will introduce appropriate notation by taking the classical orthogonal polynomials as examples.

Let \( \{ f_n(x) \}_{n=0}^{\infty} \) be a sequence of orthogonal polynomials with real coefficients. That is
$f_n(x)$ is a degree $n$ polynomial in $x$ and they are mutually orthogonal $(f_n, f_m) = h_n\delta_{n,m}$ ($h_n > 0$) with respect to an (positive definite) inner product $(f, g) = \int f(x)g(x)w(x)dx$ ($w(x)$ is a weight function). Let $f_n^{\text{monic}}(x)$ be a monic one, $f_n(x) = c_nf_n^{\text{monic}}(x) = c_n(x^n + \cdots)$. Then $f_n^{\text{monic}}(x)$ satisfies three-term recurrence:

$$f_{n+1}^{\text{monic}}(x) - (x - a_n)f_n^{\text{monic}}(x) + b_nf_{n-1}^{\text{monic}}(x) = 0, \quad (n \geq 0), \quad (2.90)$$

where we have set $f_0^{\text{monic}}(x) = 0^1$, and $a_n (n \geq 0)$ and $b_n (n \geq 1, b_0$ is unnecessary, $b_n > 0$) are real numbers. The constants $a_n$, $b_n$ and $h_n$ are given by

$$a_n = \frac{(xf_n(x), f_n(x))}{(f_n(x), f_n(x))}, \quad b_n = \frac{c_{n-1}^2}{c_n^2} \frac{(f_n(x), f_n(x))}{(f_{n-1}(x), f_{n-1}(x))}, \quad h_n = (1, 1)c_n^2\prod_{j=1}^{n}b_j. \quad (2.91)$$

Namely $f_n(x)$ satisfies the three-term recurrence

$$\frac{c_n}{c_{n+1}}f_{n+1}(x) - (x - a_n)f_n(x) + b_n\frac{c_n}{c_{n-1}}f_{n-1}(x) = 0, \quad (n \geq 0). \quad (2.92)$$

For $a_n = 0 (n \geq 0)$ case, $f_n(x)$ has a definite parity, $f_{-n}(x) = (-1)^nf_n(x)$, and the constant term of the even polynomial is

$$f_{2n}(0) = (-1)^nc_{2n}\prod_{j=1}^{n}b_{2j-1}. \quad (2.93)$$

Conversely, if \{$f_n(x)$\} is defined by the three-term recurrence \((2.90)\), namely, real numbers $a_n (n \geq 0)$, $b_n (n \geq 1, b_n > 0)$ and $c_n (n \geq 0, c_n \neq 0)$ are given, then \{$f_n(x)$\} is a sequence of orthogonal polynomials with respect to some (positive definite) inner product $(\cdot, \cdot)$.

In the rest of this subsection we summarise the three-term recurrence, generating functions, differential equations, etc for the Hermite, Laguerre and Jacobi polynomials for later comparison with the corresponding quantities of the deformed polynomials.

The Hermite polynomials $H_n(x)$ \((2.18)\) are orthogonal with respect to the inner product $(f, g) = \int_{-\infty}^{\infty} f(x)g(x)e^{-x^2}dx, (h_n = 2^n n!\sqrt{\pi})$ and satisfy the three-term recurrence \((2.90)\) with

$$a_n = 0, \quad b_n = \frac{n}{2}, \quad c_n = 2^n, \quad (2.94)$$

$$H_{n+1}(x) - 2xH_n(x) + 2nH_{n-1}(x) = 0. \quad (2.95)$$

\(^1\)Hereafter we adopt the convention $f_{-1}(x) = 0$ and $f_0(x) = 1$ for all the polynomials in this paper.
The generating function and orthogonality are

$$G(t, x) = \sum_{n=0}^{\infty} \frac{t^n}{n!} H_n(x) = e^{-t^2 + 2tx}, \quad (G(t, x), G(s, x)) = \sqrt{\pi} e^{2ts}. \quad (2.96)$$

The Laguerre polynomials $L_n^{(a)}(x)$ (2.19) are orthogonal with respect to the inner product $(f, g) = \int_0^\infty f(x)g(x)x^a e^{-x} dx$, $(h_n(\alpha) = \Gamma(\alpha + n + 1)/n!$, Re $\alpha > -1)$ and satisfy the three-term recurrence (2.90) with

$$a_n = 2n + 1 + \alpha, \quad b_n = n(n + \alpha), \quad c_n = (-1)^n/n!, \quad (2.97)$$

$$(n + 1)L_{n+1}^{(a)}(x) + (x - (2n + \alpha + 1))L_n^{(a)}(x) + (n + \alpha)L_{n-1}^{(a)}(x) = 0. \quad (2.98)$$

The Jacobi polynomials $P_n^{(\alpha, \beta)}(x)$ (2.36) are orthogonal with respect to $(f, g) = \int_{-1}^1 f(x)g(x)(1-x)^\alpha(1+x)^\beta dx$, $(h_n(\alpha, \beta) = \frac{\Gamma(\alpha + n + 1)\Gamma(\beta + n + 1)}{\Gamma(\alpha + \beta + 2n + 1)}$ and satisfy the three-term recurrence (2.90) with

$$a_n = \frac{\beta^2 - \alpha^2}{d_{2n}d_{2n+2}}, \quad b_n = 4n(n + \alpha)(n + \beta) \times \frac{d_n}{d_{2n-1}d_{2n}^2d_{2n+1}}, \quad (2.99)$$

$$c_n = 2^{-n}(\alpha^2 + \beta + 2n), \quad d_m = \alpha + \beta + m, \quad (2.100)$$

$$2(n + 1)(\alpha + \beta + n + 1)(\alpha + \beta + 2n)P_{n+1}^{(\alpha, \beta)}(x)$$

$$- (\alpha + \beta + 2n + 1)\left((\alpha + \beta + 2n)(\alpha + \beta + 2n + 2)x + \alpha^2 - \beta^2\right)P_n^{(\alpha, \beta)}(x)$$

$$+ 2(\alpha + n)(\beta + n)(\alpha + \beta + 2n + 2)P_{n-1}^{(\alpha, \beta)}(x) = 0. \quad (2.101)$$

The Gegenbauer polynomial $C_n^{(\alpha + \frac{1}{2})}(x)$ (2.35) is a special case of the Jacobi polynomial $C_n^{(\alpha + \frac{1}{2})}(x) = \frac{(2n + 1)}{n}\binom{\alpha + n}{n}^{-1} P_n^{(\alpha, \alpha)}(x)$. The Chebyshev polynomial of the first kind $T_n(x)$ is also a special case of the Jacobi polynomial $T_n(x) = 2^{-1}\binom{2n + 1}{n}^{-1} P_n^{(-\frac{1}{2}, -\frac{1}{2})}(x)$. The Legendre polynomial is $P_n(x) = P_n^{(0,0)}(x)$.

The differential equations of the Hermite, Laguerre and Jacobi polynomials are

$$\frac{d^2}{dx^2}H_n(x) - 2x \frac{d}{dx}H_n(x) + 2nH_n(x) = 0, \quad (2.102)$$

$$x \frac{d^2}{dx^2}L_n^{(a)}(x) + (\alpha + 1 - x) \frac{d}{dx}L_n^{(a)}(x) + nL_n^{(a)}(x) = 0, \quad (2.103)$$

$$(1 - x^2) \frac{d^2}{dx^2}P_n^{(\alpha,\beta)}(x) + \left(\beta - \alpha - (\alpha + \beta + 2)x\right) \frac{d}{dx}P_n^{(\alpha,\beta)}(x)$$

$$+ n(n + \alpha + \beta + 1)P_n^{(\alpha,\beta)}(x) = 0. \quad (2.104)$$
3 Deformation of the Hermite Polynomial

3.1 Linear Confining Potential Case (1 Parameter Deformation)

For the solution \(\{\bar{q}_j\}\) of the \(A_{r-1}\) equation (2.60), let us define

\[
\bar{q}_j = \sqrt{ag} y_j, \quad \delta = \frac{g}{a},
\]

and introduce a degree \(r\) polynomial in \(x\) having zeros at \(\{y_j\}\):

\[
H_r(x, \delta) \overset{\text{def}}{=} 2r \prod_{j=1}^{r} (x - y_j).
\]

(3.2)

It is a deformation of the Hermite polynomial (2.18) such that

\[
\lim_{\delta \to 0} H_r(x, \delta) = H_r(x).
\]

(3.3)

If \(\{\bar{q}_j\}\) is a solution of (2.60), so is \(\{-\bar{q}_j\}\), which would imply that the deformed polynomial \(H_r(x, \delta)\) has a definite parity

\[
H_r(-x, \delta) = (-1)^r H_r(x, \delta),
\]

(3.4)

as with the original Hermite polynomial \(H_r(-x) = (-1)^r H_r(x)\).

The equation for the equilibrium (2.60) can be written as (we replace \(r\) by \(n\))

\[
\prod_{k=1}^{n} y_j - y_k - i\sqrt{\delta} = \frac{y_j + i\sqrt{\delta}}{y_j - i\sqrt{\delta}}.
\]

(3.5)

From this equation, we obtain the following functional equation for \(H_n(x, \delta)\) \((n \geq 1)\),

\[
(x + i\frac{1}{\sqrt{\delta}}) H_n(x + i\sqrt{\delta}, \delta) - (x - i\frac{1}{\sqrt{\delta}}) H_n(x - i\sqrt{\delta}, \delta) = 2iA_n H_n(x, \delta),
\]

(3.6)

because the LHS is \(i\) times a degree \(n\) polynomial in \(x\) with real coefficients which vanishes at \(x = y_j\). Here \(A_n = A_n(\delta)\) is a real constant. This functional equation contains all the information of the equilibrium. The number of unknown coefficients (coefficient of \(x^k\) term of \(H_n(x, \delta)\) \((k = 0, 1, \ldots, n - 1)\) and \(A_n\)) and the number of equations (coefficient of \(x^k\) term of (3.6) \((k = 0, 1, \ldots, n)\)) are both \(n\). The constant \(A_n\) is determined by the coefficient of \(x^n\) term of this equation,

\[
A_n = \frac{1}{\sqrt{\delta}} (1 + n\delta).
\]

(3.7)
The functional equation (3.6) can be written as a difference equation,

\[ D_{x,i\sqrt{\delta}}^2 H_n(x,\delta) - 2xD_{x,i\sqrt{\delta}} H_n(x,\delta) + 2nH_n(x,\delta) = 0, \]

(3.8)

where \( D_{x,h} \) is a (central) difference operator,

\[ D_{x,h}f(x) = \frac{f(x+h) - f(x-h)}{2h}. \]

(3.9)

In the \( \delta \to 0 \) limit, (3.6) reduces to the differential equation of the Hermite polynomial (2.102).

The uniqueness (up to normalisation) of the solution of the functional equation (3.6) is easily shown (Proposition A.1). Therefore it is sufficient to construct one solution of (3.6) explicitly. This is done by using the three-term recurrence (see Appendix). The result is as follows; The functional equation (3.6) implies that the deformed Hermite polynomial \( H_n(x,\delta) \) satisfies the three-term recurrence (2.90) with

\[ a_n = 0, \quad b_n = \frac{n}{2} \left( 1 + \frac{n-1}{2} \delta \right), \quad c_n = 2^n, \]

(3.10)

\[ H_{n+1}(x,\delta) - 2xH_n(x,\delta) + \left( 2n + n(n-1)\delta \right) H_{n-1}(x,\delta) = 0. \]

(3.11)

Since \( \delta \) is positive in this case (3.1), \( b_n \) is also positive. Therefore \( H_n(x,\delta) \) is a set of orthogonal polynomials with respect to some positive definite inner product.

Here we present another derivation of this three-term recurrence. Let us consider the generating function

\[ G(t, x, \delta) = \sum_{n=0}^{\infty} \frac{t^n}{n!} H_n(x, \delta), \]

(3.12)

which satisfies

\[ \left( (1 + \delta t^2) \frac{\partial}{\partial t} + 2(t - x) \right) G(t, x, \delta) = 0, \]

(3.13)

as a consequence of the three-term recursion (3.11). This linear differential equation with the initial condition \( G(0, x, \delta) = 1 \) can be easily solved and we obtain

\[ G(t, x, \delta) = \frac{\exp(2x \arctan \sqrt{\delta} t)}{(1 + \delta t^2)^{1/2}}. \]

(3.14)

In the \( \delta \to 0 \) limit, this generating function tends to that of the Hermite polynomial (2.96),

\[ \lim_{\delta \to 0} G(t, x, \delta) = e^{-t^2} e^{2xt} = e^{-t^2+2xt} = G(t, x). \]

(3.15)
The functional equation of $G(t, x, \delta)$ is obtained from (3.6):

\[
(x + i \frac{1}{\sqrt{\delta}}) G(t, x + i \sqrt{\delta}, \delta) - (x - i \frac{1}{\sqrt{\delta}}) G(t, x - i \sqrt{\delta}, \delta) = \frac{2i}{\sqrt{\delta}} (1 + \delta t \frac{\partial}{\partial t}) G(t, x, \delta). \tag{3.16}
\]

Since the solution of (3.6) is unique (up to normalization), it is sufficient to show that (3.14) satisfies this functional equation. This can be easily verified by explicit calculation, in which the following formula derived from (3.14) is useful,

\[
G(t, x \pm i \sqrt{\delta}, \delta) = 1 \pm i \sqrt{\delta t} G(t, x, \delta). \tag{3.17}
\]

The explicit form of the inner product $(f, g) = \int_{-\infty}^{\infty} f(x) g(x) w(x, \delta) dx$, i.e., the weight function $w(x, \delta)$ is determined by using the generating function. Here we list main results only without derivation. Let us fix its normalisation by $(1, 1)_\delta = \sqrt{\pi}$. From the general theory (2.91), the orthogonality of $H_n(x, \delta)$ is

\[
(H_n(x, \delta), H_m(x, \delta))_\delta = \delta_{n,m} h_n, \quad h_n = \sqrt{\pi} 2^n n! \prod_{j=0}^{n-1} (1 + \frac{1}{2} j \delta), \tag{3.18}
\]

which leads to

\[
(G(t, x, \delta), G(s, x, \delta))_\delta = \sqrt{\pi} (1 - \delta ts)^{-\frac{\delta}{2}}. \tag{3.19}
\]

Here we have used the identity

\[
F(x) = \sum_{n=0}^{\infty} \frac{x^n}{n!} \prod_{j=0}^{n-1} (1 + \frac{1}{2} j \delta) = (1 - \frac{1}{2} \delta x)^{-\frac{\delta}{2}}. \tag{3.20}
\]

The weight function is expressed as

\[
w(x, \delta) = \int_{-\infty}^{\infty} dt \frac{\cos 2xt}{\sqrt{\pi} \left( \cosh \sqrt{\delta} t \right)^{\frac{\delta}{2}}} = \frac{2^{\frac{\delta}{2}-1}}{\sqrt{\pi} \delta} B \left( \frac{1}{\delta} + i \frac{x}{\sqrt{\delta}}, \frac{1}{\delta} - i \frac{x}{\sqrt{\delta}} \right) \tag{3.21}
\]

\[
= \frac{2^{\frac{\delta}{2}-1} \Gamma \left( \frac{1}{\delta} + i \frac{x}{\sqrt{\delta}} \right) \Gamma \left( \frac{1}{\delta} - i \frac{x}{\sqrt{\delta}} \right)}{\Gamma \left( \frac{2}{\delta} \right)} = \frac{2^{\frac{\delta}{2}-1} |\Gamma \left( \frac{1}{\delta} + i \frac{x}{\sqrt{\delta}} \right)|^2}{\sqrt{\pi} \delta} \tag{3.22}
\]

The undeformed limit of the weight function $\lim_{\delta \to 0} w(x, \delta) = e^{-x^2}$ can be verified by using the asymptotic expansion of the $\Gamma$-function. The Taylor series of $w(x, \delta)$ in powers of $\delta$ reads

\[
w(x, \delta) = e^{-x^2} \left( 1 + \frac{\delta}{24} (3 - 12 x^2 + 4x^4) + \frac{\delta^2}{5760} (45 - 1320 x^2 + 2280 x^4 - 864 x^6 + 80 x^8) + \frac{\delta^3}{2903040} (-14175 + 71820 x^2 + 865620 x^4 - 1042272 x^6 + 386928 x^8 - 52416 x^{10} + 2240 x^{12}) + \cdots \right). \tag{3.23}
\]
Among many interesting properties of $H_n(x, \delta)$, we present only

(i) $H_{2n}(0, \delta) = (-1)^n \frac{(2n)!}{n!} \prod_{j=0}^{n-1} (1 + j\delta)$, see (2.93), (3.24)

(ii) $\frac{d}{dx} H_n(x, \delta) = 2 \sum_{k=0}^{\left\lfloor \frac{n}{2} \right\rfloor} (2k)! \left( \frac{n}{2k+1} \right) (-\delta)^{k} H_{n-1-2k}(x, \delta)$, (3.25)

which is a deformation of $\frac{d}{dx} H_n(x) = 2n H_n(x)$.

Remark: We may take the three-term recurrence (3.11) as the definition of the deformed Hermite polynomial $H_n(x, \delta)$ for an arbitrary (complex) parameter $\delta$. Then $H_n(x, \delta)$ is a polynomial in $x$ of degree $n$ and in $\delta$ of degree $\left\lfloor \frac{n}{2} \right\rfloor$ with integer coefficients. We will not repeat similar remarks which are valid for almost all of the deformed polynomials in this paper.

### 3.2 Quadratic Confining Potential Case (2 Parameter Deformation)

For the solution $\{\bar{q}_j\}$ of the $A_{r-1}$ equation (2.69), let us define

$$\bar{q}_j = \sqrt{ag} y_j, \quad \delta = \frac{g}{a}, \quad \varepsilon = \frac{a}{b},$$

and introduce a degree $r$ polynomial in $x$ having zeros at $\{y_j\}$:

$$H_r(x, \delta, \varepsilon) \overset{\mathrm{def}}{=} 2^r \prod_{j=1}^{r} (x - y_j).$$

It is a further deformation of the deformed Hermite polynomial defined previously,

$$\lim_{\varepsilon \to 0} H_r(x, \delta, \varepsilon) = H_r(x, \delta), \quad H_r(-x, \delta, \varepsilon) = (-1)^r H_r(x, \delta, \varepsilon).$$

The symmetry between the two parameters $a \leftrightarrow b$ is expressed as

$$H_r(x, \delta \varepsilon, \varepsilon^{-1}) = \varepsilon^{\frac{r}{2}} H_r(\varepsilon^{-\frac{1}{2}} x, \delta, \varepsilon).$$

If we define $\hat{H}_r(x, \delta_1) \overset{\mathrm{def}}{=} \frac{q}{a} = \delta, \hat{\delta}_2 \overset{\mathrm{def}}{=} \frac{q}{b} = \delta\varepsilon \overset{\mathrm{def}}{=} \sqrt{1 + \varepsilon} H_r(\frac{x}{\sqrt{1 + \varepsilon}}, \delta, \varepsilon)$, then this symmetry is more manifest, $\hat{H}_r(x, \delta_1, \delta_2) = \hat{H}_r(x, \delta_2, \delta_1)$.

The equation for the equilibrium (2.69) can be written as (we replace $r$ by $n$)

$$\prod_{j=1}^{n} \frac{y_j - y_k - i\sqrt{\delta}}{y_j - y_k + i\sqrt{\delta}} = -\frac{y_j + i\frac{1}{\sqrt{\delta}}}{y_j - i\frac{1}{\sqrt{\delta}}} \frac{y_j + i\frac{1}{\sqrt{\delta}}}{y_j - i\frac{1}{\sqrt{\delta}}}.$$ (3.30)
From this equation, we obtain the following functional equation for $H_n(x, \delta, \varepsilon) \ (n \geq 1)$,
\[
(x + \frac{i}{\sqrt{\delta}})(x + \frac{1}{\varepsilon\sqrt{\delta}})H_n(x + i\sqrt{\delta}, \delta, \varepsilon) + (x - \frac{i}{\sqrt{\delta}})(x - \frac{1}{\varepsilon\sqrt{\delta}})H_n(x - i\sqrt{\delta}, \delta, \varepsilon) = 2(A_n x^2 + B_n x + C_n)H_n(x, \delta, \varepsilon),
\]
(3.31)
because the LHS is a degree $n + 2$ polynomial in $x$ with real coefficients which vanishes at $x = y_j$. Here $A_n = A_n(\delta, \varepsilon)$, $B_n = B_n(\delta, \varepsilon)$ and $C_n = C_n(\delta, \varepsilon)$ are real constants:
\[
A_n = 1, \quad B_n = 0, \quad C_n = -\left(\left(\frac{1}{\delta} + n\varepsilon^{-1} + n + \frac{1}{2}n(n-1)\delta\right)\right).
\]
(3.32)
This functional equation contains all the information of the equilibrium. The above functional equation (3.31) reduces to that of $H_n(x, \delta) \ (3.6)$ in a proper limit $\varepsilon \to 0$. This functional equation can be written as a difference equation,
\[
(1 - \delta \varepsilon x^2)D^2_{x, \frac{i}{\varepsilon\sqrt{\delta}}}H_n(x, \delta, \varepsilon) - 2(1 + \varepsilon)x D_{x, \frac{i}{\varepsilon\sqrt{\delta}}}H_n(x, \delta, \varepsilon) + 2n(1 + (1 + \frac{n-1}{2}\delta)\varepsilon)H_n(x, \delta, \varepsilon) = 0.
\]
(3.33)
The functional equation (3.31) implies (see Appendix) the three-term recurrence (2.90) for the deformed Hermite polynomial $H_n(x, \delta, \varepsilon)$ with
\[
a_n = 0, \quad b_n = \frac{n}{2}\left(1 + \frac{n-1}{2}\delta\right)\left(1 + \frac{n-1}{2}\delta\varepsilon\right)\frac{d_n}{d_{2n-1}d_{2n+1}}, \quad c_n = 2^n,
\]
(3.34)
\[
d_m = 1 + \left(1 + \frac{m-2}{2}\delta\right)\varepsilon,
\]
(3.35)
\[
H_{n+1}(x, \delta, \varepsilon) - 2xH_n(x, \delta, \varepsilon) + \left(2n + n(n-1)\delta\right)\frac{d_n}{d_{2n-1}d_{2n+1}}H_{n-1}(x, \delta, \varepsilon) = 0.
\]
(3.36)
Since $\delta$ and $\varepsilon$ are positive in this case (3.26), $b_n$ is also positive. From this three-term recurrence we obtain the differential equation for the generating function $G(t, x, \delta, \varepsilon) = \sum_{n=0}^{\infty} \frac{t^n}{n!}H_n(x, \delta, \varepsilon)$,
\[
\left((d_{2n-1}d_{2n+1}) \mid \frac{\partial}{\partial t} - 2x + \left(\frac{4}{n}d_{2n-1}d_{2n+1}b_n\right) \mid \frac{\partial}{\partial t}\right)G(t, x, \delta, \varepsilon) = 0,
\]
(3.37)
which is a third order linear differential equation with respect to $t$. The special case $\delta = 0$ gives the original Hermite polynomial, $H_n(x, 0, \varepsilon) = (\sqrt{\varepsilon - 1})^{-n}H_n(\sqrt{\varepsilon - 1} x)$. The value at the origin of the even polynomial shows a characteristic deformation pattern, see (2.49):
\[
H_{2n}(0, \delta, \varepsilon) = (-1)^n \frac{(2n)!}{n!} \prod_{j=0}^{n-1} \frac{(1 + j\delta)(1 + j\delta\varepsilon)}{1 + (1 + (j + n - \frac{1}{2})\delta)\varepsilon}.
\]
(3.38)
4 Deformation of the Laguerre Polynomial

4.1 Linear Confining Potential Case (1 or 2 Parameter Deformation)

\( \widetilde{BC}_r \): For the solution \( \{ \tilde{q}_j \} \) of the \( \widetilde{BC}_r \) equation [4.1], let us define

\[
\tilde{q}_j = \sqrt{a g_0} y_j, \quad \delta = \frac{g_0}{a}, \quad \alpha = \frac{g_1 + g_2}{g_0} - 1, \quad \gamma = \frac{g_1 g_2}{\delta}, \tag{4.1}
\]

and introduce a degree \( r \) polynomial in \( x \), having zeros at \( \{ y_j^2 \} \):

\[
L_r^{(\alpha)}(x, \gamma, \delta) \overset{\text{def}}{=} \frac{(-1)^r}{r!} \prod_{j=1}^r (x - y_j^2).	ag{4.2}
\]

It is a two parameter deformation of the Laguerre polynomial such that

\[
\lim_{\delta \to 0} L_r^{(\alpha)}(x, \gamma, \delta) = L_r^{(\alpha)}(x). \tag{4.3}
\]

The equation for the equilibrium (2.63) can be written as (we replace \( r \) by \( n \))

\[
\prod_{k=1}^n \frac{(y_j - i \sqrt{\delta})^2 - y_k^2}{(y_j + i \sqrt{\delta})^2 - y_k^2} = \frac{y_j - i \frac{\sqrt{\delta}}{2} y_j + i \frac{1}{\sqrt{\delta}} y_j^2 + i(\alpha + 1)\sqrt{\delta} y_j - \gamma \delta}{y_j + i \frac{\sqrt{\delta}}{2} y_j - i \frac{1}{\sqrt{\delta}} y_j^2 - i(\alpha + 1)\sqrt{\delta} y_j - \gamma \delta}. \tag{4.4}
\]

From this equation, we obtain the following functional equation for \( L_n^{(\alpha)}(x, \gamma, \delta) \) \( (n \geq 1) \),

\[
\frac{1}{y} \left( \left( y - i \frac{\sqrt{\delta}}{2} \right) \left( y + i \frac{1}{\sqrt{\delta}} \right) \left( y^2 + i(\alpha + 1)\sqrt{\delta} y - \gamma \delta \right) L_n^{(\alpha)} \left( (y + i \sqrt{\delta})^2, \gamma, \delta \right) \right. \\
\left. - \left( y + i \frac{\sqrt{\delta}}{2} \right) \left( y - i \frac{1}{\sqrt{\delta}} \right) \left( y^2 - i(\alpha + 1)\sqrt{\delta} y - \gamma \delta \right) L_n^{(\alpha)} \left( (y - i \sqrt{\delta})^2, \gamma, \delta \right) \right)
= 2i (A_n y^2 + B_n) L_n^{(\alpha)}(y^2, \gamma, \delta), \tag{4.5}
\]

because the LHS is \( i \) times a degree \( 2n + 2 \) even polynomial in \( y \) with real coefficients which vanishes at \( y = \pm y_j \). Here \( A_n = A_n^{(\alpha)}(\gamma, \delta) \) and \( B_n = B_n^{(\alpha)}(\gamma, \delta) \) are real constants:

\[
A_n = \frac{1}{\sqrt{\delta}} \left( 1 + (2n + \alpha + \frac{1}{2})\delta \right), \quad B_n = \frac{\sqrt{\delta}}{2} \left( \alpha + 1 - 2\gamma + (n + \gamma)\delta \right). \tag{4.6}
\]

This functional equation contains all the information of the equilibrium. The functional equation can be written as a difference equation,

\[
\left( (1 + (\alpha + \frac{1}{2})\delta)y^2 + (\frac{\alpha + 1}{2} - \gamma)\delta + \frac{1}{2}\gamma^2\delta^2 \right) D_{y, \frac{\sqrt{\delta}}{2}} L_n^{(\alpha)}(y^2, \gamma, \delta) \\
+ \left(-2y^3 + (2\alpha + 1 + (2\gamma - \alpha - 1)\delta)y + \gamma \delta y^{-1} \right) D_{y, \frac{\sqrt{\delta}}{2}} L_n^{(\alpha)}(y^2, \gamma, \delta) \\
+(4ny^2 + n\delta)L_n^{(\alpha)}(y^2, \gamma, \delta) = 0. \tag{4.7}
\]
In the $\delta \to 0$ limit, it becomes,
\[
y \frac{d^2}{dy^2} L_n^{(\alpha)}(y^2) + (2\alpha + 1 - 2y^2) \frac{d}{dy} L_n^{(\alpha)}(y^2) + 4nyL_n^{(\alpha)}(y^2) = 0,
\]
which is equivalent to the differential equation of the Laguerre polynomial \[2.13\].

By the same argument as $H_n(x, \delta)$, see Appendix, the functional equation \[4.5\] implies that the deformed Laguerre polynomial $L_n^{(\alpha)}(x, \gamma, \delta)$ satisfies the three-term recurrence \[2.90\] with
\[
a_n = 2n + \alpha + 1 + (n(2n + 1) + 2n\alpha + \gamma)\delta,
b_n = n(n + \alpha)
      \left(1 + (2n + \alpha - 1)\delta + ((n - 1)(n + \alpha) + \gamma)\delta^2\right),\quad
c_n = (-1)^n/n!,
\]
\[
(n + 1)L_{n+1}^{(\alpha)}(x, \gamma, \delta) + \left(x - (2n + \alpha + 1 + n(2n + 1) + 2n\alpha + \gamma)\delta\right)L_n^{(\alpha)}(x, \gamma, \delta)
+ (n + \alpha)
      \left(1 + (2n + \alpha - 1)\delta + ((n - 1)(n + \alpha) + \gamma)\delta^2\right)L_{n-1}^{(\alpha)}(x, \gamma, \delta) = 0.
\]

In this case \[4.1\], the parameter ranges are $\delta, \gamma > 0$ and $\alpha > -1$. So $b_n$ is positive. Therefore $L_n^{(\alpha)}(x, \gamma, \delta)$ is a set of orthogonal polynomials with respect to some positive definite inner product. From this three-term recurrence we obtain the differential equation for the generating function
\[
G^{(\alpha)}(t, x, \gamma, \delta) = \sum_{n=0}^{\infty} t^n L_n^{(\alpha)}(x, \gamma, \delta),
\]
\[
\left(\frac{\partial}{\partial t} + x - a_n \bigg|_{n \rightarrow t \frac{\partial}{\partial t}} + \frac{b_n}{n} \bigg|_{n \rightarrow t \frac{\partial}{\partial t}} t\right)G^{(\alpha)}(t, x, \gamma, \delta) = 0,
\]
which is a third order linear differential equation with respect to $t$.

$C_r$: For the solution $\{\bar{q}_j\}$ of the $C_r$ equation \[2.62\], let us define
\[
\bar{q}_j = \sqrt{ags} \, y_j, \quad \delta = \frac{gs}{a}, \quad \alpha = \frac{gL}{gs} - 1,
\]
and introduce a degree $r$ polynomial in $x$, having zeros at $\{y_j^2\}$:
\[
L_r^{(\alpha)}(x, \delta) \overset{\text{def}}{=} \frac{(-1)^r}{r!} \prod_{j=1}^{r} (x - y_j^2).
\]
This is a deformation of the Laguerre polynomial such that $\lim_{\delta \to 0} L_r^{(\alpha)}(x, \delta) = L_r^{(\alpha)}(x)$, and obviously it is a special case of $L_n^{(\alpha)}(x, \gamma, \delta)$,
\[
L_n^{(\alpha)}(x, \delta) = L_n^{(\alpha)}(x, 0, \delta).
\]
The functional equation for $L_n^{(\alpha)}(x, \delta)$ is easily obtained from that of $L_n^{(\alpha)}(x, \gamma, \delta)$ and will not be presented. The three-term recurrence for $L_n^{(\alpha)}(x, \delta)$ reads

$$
(n + 1) L_{n+1}^{(\alpha)}(x, \delta) + \left( x - (2n + \alpha + 1 + n(2n + 2\alpha + 1)) \right) L_n^{(\alpha)}(x, \delta) \\
+ (n + \alpha) \left( 1 + (n - 1) \delta \right) \left( 1 + (n + \alpha) \delta \right) L_{n-1}^{(\alpha)}(x, \delta) = 0,
$$

(4.16)

The value at the origin shows a simple deformation pattern

$$L_n^{(\alpha)}(0, \delta) = \left( \frac{n + \alpha}{n} \right)^{n-1} \prod_{j=0}^{n-1} (1 + j \delta).
$$

(4.17)

B$\_r$: For the solution $\{\bar{q}_j\}$ of the $B_r$ equation (2.61), let us define

$$\bar{q}_j = \sqrt{a_g L} y_j, \quad \delta = \frac{g_L}{a}, \quad \alpha = \frac{g_S}{g_L} - 1,
$$

(4.18)

and introduce a degree $r$ polynomial in $x$, having zeros at $\{y_j^2\}$:

$$\tilde{L}_r^{(\alpha)}(x, \delta) \overset{\text{def}}{=} \frac{(-1)^r}{r!} \prod_{j=1}^{r} (x - y_j^2).
$$

(4.19)

This is a deformation of the Laguerre polynomial such that $\lim_{\delta \to 0} \tilde{L}_r^{(\alpha)}(x, 0) = L_r^{(\alpha)}(x)$, and obviously it is a special case of $L_n^{(\alpha)}(x, \gamma, \delta)$

$$\tilde{L}_n^{(\alpha)}(x, \delta) = L_n^{(\alpha)}(x, \frac{1}{4}(\alpha + 1)^2, \delta).
$$

(4.20)

The functional equation of $\tilde{L}_n^{(\alpha)}(x, \delta)$ is easily obtained from that of $L_n^{(\alpha)}(x, \gamma, \delta)$ and will not be presented. The three-term recurrence for $\tilde{L}_n^{(\alpha)}(x, \delta)$ reads

$$
(n + 1) \tilde{L}_{n+1}^{(\alpha)}(x, \delta) + \left( x - (2n + \alpha + 1 + n(2n + 2\alpha + 1)) + \frac{1}{4}(\alpha + 1)^2 \right) \tilde{L}_n^{(\alpha)}(x, \delta) \\
+ (n + \alpha) \left( 1 + (n + \frac{\alpha - 1}{2}) \delta \right)^2 \tilde{L}_{n-1}^{(\alpha)}(x, \delta) = 0.
$$

(4.21)

D$\_r$: As in the Calogero systems, the $D_r$ is a special case $g_S = 0$ of the $B_r$ theory described by $\tilde{L}_r^{(-1)}(x, \delta) = L_r^{(-1)}(x, \delta)$, which has a zero at $x = 0$ for all $r$. 

26
4.2 Quadratic Confining Potential Case (2 or 3 Parameter Deformation)

$\bar{BC}_r$: For the solution $\{\tilde{q}_j\}$ of the $\bar{BC}_r$ equation (2.72), let us define

$$\tilde{q}_j = \sqrt{ag_0} y_j, \quad \delta = \frac{g_0}{a}, \quad \varepsilon = \frac{b}{a}, \quad \alpha = \frac{g_1 + g_2}{g_0} - 1, \quad \gamma = \frac{g_1 g_2}{g_0^2}, \quad (4.22)$$

and introduce a degree $r$ polynomial in $x$, having zeros at $\{y_j^2\}$:

$$L_r^{(\alpha)}(x, \gamma, \delta, \varepsilon) \overset{\text{def}}{=} \frac{(-1)^r}{r!} \prod_{j=1}^{r} (x - y_j^2). \quad (4.23)$$

It is a further deformation of the deformed Laguerre polynomial defined previously,

$$\lim_{\varepsilon \to 0} L_r^{(\alpha)}(x, \gamma, \delta, \varepsilon) = L_r^{(\alpha)}(x, \gamma, \delta). \quad (4.24)$$

The symmetry between the two parameters $a \leftrightarrow b$ is expressed as

$$L_r^{(\alpha)}(x, \gamma, \delta, \varepsilon, \varepsilon^{-1}) = \varepsilon^r L_r^{(\alpha)}(x, \gamma, \delta, \varepsilon). \quad (4.25)$$

If we define $\hat{L}_r^{(\alpha)}(x, \gamma, \delta_1) \overset{\text{def}}{=} \frac{q}{a} = \delta_1, \delta_2 \overset{\text{def}}{=} \frac{q}{b} = \delta_2 \overset{\text{def}}{=} (1+\varepsilon)^r \hat{L}_r^{(\alpha)}(x, \gamma, \delta, \varepsilon)$, then this symmetry is more manifest, $\hat{L}_r^{(\alpha)}(x, \gamma, \delta_1, \delta_2) = \hat{L}_r^{(\alpha)}(x, \gamma, \delta_2, \delta_1)$.

The equation for the equilibrium (2.72) can be written as (we replace $r$ by $n$)

$$\prod_{k=1}^{n} \left( y_j - i\sqrt{\delta} \right)^2 - y_k^2 = \frac{y_j - i\sqrt{\delta}}{y_j + i\sqrt{\delta}} y_j + i \frac{1}{\sqrt{\delta}} y_j + i \frac{1}{\sqrt{\delta}} y_j^2 + i(\alpha + 1) \sqrt{\delta} y_j - \gamma \delta. \quad (4.26)$$

The equivalent functional equation for $L_n^{(\alpha)}(x, \gamma, \delta, \varepsilon)$ ($n \geq 1$) reads

$$\frac{1}{y} \left( y - i\frac{\sqrt{\delta}}{2} \right) \left( y + i \frac{1}{\varepsilon \sqrt{\delta}} \right) \left( y + i \frac{1}{\varepsilon \sqrt{\delta}} \right) \left( y^2 + i(\alpha + 1) \sqrt{\delta} y - \gamma \delta \right) L_n^{(\alpha)}(y + i\sqrt{\delta}) \gamma, \delta, \varepsilon \right)$$

$$+ \left( y + i\frac{\sqrt{\delta}}{2} \right) \left( y - i \frac{1}{\varepsilon \sqrt{\delta}} \right) \left( y - i \frac{1}{\varepsilon \sqrt{\delta}} \right) \left( y^2 - i(\alpha + 1) \sqrt{\delta} y - \gamma \delta \right) L_n^{(\alpha)}(y - i\sqrt{\delta}) \gamma, \delta, \varepsilon \right)$$

$$= 2(A_n y^4 + B_n y^2 + C_n) L_n^{(\alpha)}(y^2, \gamma, \delta, \varepsilon), \quad (4.27)$$

because the LHS is a degree $2n + 4$ even polynomial in $y$ with real coefficients which vanishes at $y = \pm y_j$. Here $A_n = A_n^{(\alpha)}(\gamma, \delta, \varepsilon), B_n = B_n^{(\alpha)}(\gamma, \delta, \varepsilon)$ and $C_n = C_n^{(\alpha)}(\gamma, \delta, \varepsilon)$ are real constants:

$$A_n = 1, \quad (4.28)$$

$$B_n = -(\delta^{-1} + 2n + \alpha + \frac{1}{2})\varepsilon^{-1} - (2n + \alpha + \frac{1}{2}) - \left( \gamma - 2n + 2n(n + \alpha) \right) \delta, \quad (4.29)$$

$$C_n = -\frac{1}{2} \left( \alpha + 1 - 2\gamma + (n + \gamma)\delta \right) \varepsilon^{-1} - \frac{1}{2}(n + \gamma)\delta - \frac{1}{2}n(n + \alpha)\delta^2. \quad (4.30)$$
This functional equation contains all the information of the equilibrium. In a proper limit 
$\varepsilon \to 0$, the above functional equation \[4.27\] reduces to that of $L_n^{(\alpha)}(x, \gamma, \delta)$ \[4.5\]. This 
functional equation can be written as a difference equation as previous examples.

The functional equation \[4.27\] implies (see Appendix) that the deformed Laguerre poly-
nomial $L_n^{(\alpha)}(x, \gamma, \delta, \varepsilon)$ satisfies the three-term recurrence \[2.30\] with,

$$
a_n = 2n + \alpha + 1 + \frac{X_0 + X_1\varepsilon + X_2\varepsilon^2}{d_2nd_{2n+2}},
$$

$$
b_n = n(n + \alpha) \left(1 + (2n + \alpha - 1)\delta + ((n - 1)(n + \alpha) + \gamma)\delta^2\right)
\times \left(1 + (1 + (n - 1)\delta)\varepsilon\right) \left(1 + (2n + \alpha - 1)\delta\varepsilon + ((n - 1)(n + \alpha) + \gamma)\delta^2\varepsilon^2\right)
\times \frac{d_n}{d_{2n-1}d_{2n}d_{n+1}},
$$

$$
c_n = (-1)^n/n!,
$$

$$
d_m = 1 + (1 + (m + \alpha - 1)\delta)\varepsilon.
$$

Here $X_0$, $X_1$ and $X_2$ are

$$
X_0 = \left(n(2n + 1) + 2n\alpha + \gamma\right)\delta,
$$

$$
X_1 = -(2n + \alpha + 1) - \left(2n(n + \alpha + 1) + (\alpha + 1)^2 - 2\gamma\right)\delta
+ \left(n(4n^2 + (6\alpha + 1)n + 2\alpha^2 - 1) + (2n + \alpha - 1)\gamma\right)\delta^2,
$$

$$
X_2 = -(2n + \alpha + 1) - \left(6n^2 + 3(2\alpha + 1)n + 2\alpha(\alpha + 1) - \gamma\right)\delta
- \left(4n^3 + 3(2\alpha + 1)n^2 + (4\alpha^2 + 4\alpha - 1)n + (\alpha - 1)(\alpha + 1)^2 - (2n + \alpha - 1)\gamma\right)\delta^2
+ n(n + \alpha) \left(2n(n + \alpha) - \alpha - 1 + 2\gamma\right)\delta^3.
$$

Namely $L_n^{(\alpha)}(x, \gamma, \delta, \varepsilon)$ satisfies

$$
(n + 1)L_{n+1}^{(\alpha)}(x, \gamma, \delta, \varepsilon) + (x - a_n)L_n^{(\alpha)}(x, \gamma, \delta, \varepsilon) + \frac{1}{n} b_n L_{n-1}^{(\alpha)}(x, \gamma, \delta, \varepsilon) = 0.
$$

In this case \[4.22\], the parameter ranges are $\delta, \varepsilon, \gamma > 0$ and $\alpha > -1$. So $b_n$ is positive. From
this three-term recurrence we obtain the differential equation for the generating function

$$
G^{(\alpha)}(t, x, \gamma, \delta, \varepsilon) = \sum_{n=0}^{\infty} t^n L_n^{(\alpha)}(x, \gamma, \delta, \varepsilon),
$$

$$
\left. \left((d_{2n-1}d_{2n}^2d_{2n+1}d_{2n+2}) \left(\frac{\partial}{\partial t} + x\right) - (d_{2n-1}d_{2n}^2d_{2n+1}d_{2n+2}a_n) \right|_{n=t} \right) + \left(\frac{1}{n} d_{2n-1}d_{2n}^2d_{2n+1}d_{2n+2}b_n \right) \left|_{n=t} \right) = 0,
$$

which is an 8-th order linear differential equation with respect to $t$. The special case of $\delta = 0$
gives the original Laguerre polynomial, $L_n^{(\alpha)}(x, \gamma, 0, \varepsilon) = (1 + \varepsilon)^{-n} L_n^{(\alpha)}((1 + \varepsilon)x)$.

28
For the solution \( \{ \bar{q}_j \} \) of the \( Cr \) equation (2.71), let us define
\[
\bar{q}_j = \sqrt{ag_{s} y_j}, \quad \delta = \frac{g_s}{a}, \quad \varepsilon = \frac{b}{a}, \quad \alpha = \frac{g_{s}}{g_{L}} - 1, \quad (4.39)
\]
and introduce a degree \( r \) polynomial in \( x \), having zeros at \( \{ y_j^2 \} \):
\[
L^{(\alpha)}_r(x, \delta, \varepsilon) \overset{\text{def}}{=} \frac{(-1)^r}{r!} \prod_{j=1}^{r} (x - y_j^2). \quad (4.40)
\]
This is a further deformation of the deformed Laguerre polynomial defined previously such that
\[
\lim_{\varepsilon \to 0} L^{(\alpha)}_r(x, \delta, \varepsilon) = \tilde{L}^{(\alpha)}_r(x, \delta) \quad (4.19),
\]
and obviously it is a special case of \( L^{(\alpha)}_r(x, \gamma, \delta, \varepsilon) \).
\[
L^{(\alpha)}_r(x, \delta, \varepsilon) = L^{(\alpha)}_r(x, 0, \delta, \varepsilon). \quad (4.41)
\]
The value at the origin shows a characteristic deformation pattern
\[
L^{(\alpha)}_n(0, \delta, \varepsilon) = \left( 1 + n + \frac{\alpha}{n} \right) \frac{1}{1 + (1 + (\alpha + j + r)\delta)\varepsilon} \prod_{j=0}^{n-1} \frac{(1 + j\delta)(1 + j\delta\varepsilon)}{1 + (1 + (\alpha + j + r)\delta)\varepsilon}. \quad (4.42)
\]

For the solution \( \{ \bar{q}_j \} \) of the \( Br \) equation (2.70), let us define
\[
\bar{q}_j = \sqrt{ ag_{L} y_j }, \quad \delta = \frac{g_{L}}{a}, \quad \varepsilon = \frac{b}{a}, \quad \alpha = \frac{g_{s}}{g_{L}} - 1, \quad (4.43)
\]
and introduce a degree \( r \) polynomial in \( x \), having zeros at \( \{ y_j^2 \} \):
\[
\tilde{L}^{(\alpha)}_r(x, \delta, \varepsilon) \overset{\text{def}}{=} \frac{(-1)^r}{r!} \prod_{j=1}^{r} (x - y_j^2). \quad (4.44)
\]
This is a further deformation of the deformed Laguerre polynomial defined previously such that
\[
\lim_{\varepsilon \to 0} \tilde{L}^{(\alpha)}_r(x, \delta, \varepsilon) = \tilde{L}^{(\alpha)}_r(x, \delta) \quad (4.19),
\]
and obviously it is a special case of \( L^{(\alpha)}_r(x, \gamma, \delta, \varepsilon) \).
\[
\tilde{L}^{(\alpha)}_r(x, \delta, \varepsilon) = L^{(\alpha)}_r(x, \frac{1}{4}(\alpha + 1)^2, \delta, \varepsilon). \quad (4.45)
\]
As in the Calogero systems, the \( Dr \) is a special case \( g_s = 0 \) of the \( Br \) theory described by
\[
\tilde{L}^{(-1)}_r(x, \delta, \varepsilon) = L^{(-1)}_r(x, \delta, \varepsilon), \quad (4.44)
\]
which has a zero at \( x = 0 \) for all \( r \).

**Deformation of the identities**: Before going to the systems with trigonometric potentials, let us present the one and two parameter deformation of the identities between the
Hermite and Laguerre polynomials, (2.20) and (2.21), which could be considered as consequences of the folding (2.5)–(2.7) and (2.50)–(2.52) of the rational potentials. The one and two parameter deformation of the even degree identities (2.20) are

\[ 2^{-2r} H_{2r}(x, \delta) = (-1)^r r! L_r^{(-\frac{1}{2})}(x^2, \delta), \]

\[ 2^{-2r} H_{2r}(x, \delta, \varepsilon) = (-1)^r r! L_r^{(-\frac{1}{2})}(x^2, \frac{1}{2}, \delta, \varepsilon), \]

which are connected with the folding \( A_{2r-1} \rightarrow C_r \) (2.3). The one and two parameter deformation of the odd degree identities (2.21) are

\[ 2^{-2r-1} H_{2r+1}(x, \delta) = x(-1)^r r! L_r^{(-\frac{1}{2})}(x^2, \frac{1}{2}, \delta), \]

\[ 2^{-2r-1} H_{2r+1}(x, \delta, \varepsilon) = x(-1)^r r! L_r^{(-\frac{1}{2})}(x^2, \frac{1}{2}, \delta, \varepsilon), \]

which are related to the folding \( A_{2r} \rightarrow \tilde{BC}_r \) (2.7). The one and two parameter deformation of the identities between Laguerre polynomials (2.22) are

\[ (r + 1) \tilde{L}_{r+1}^{(-1)}(x, \delta) = -x \tilde{L}_r^{(1)}(x, \delta), \]

\[ (r + 1) \tilde{L}_{r+1}^{(-1)}(x, \delta, \varepsilon) = -x \tilde{L}_r^{(1)}(x, \delta, \varepsilon), \]

which are related to the folding \( D_{r+1} \rightarrow B_r \) (2.6).

5 Deformation of the Jacobi Polynomial

5.1 \( A_{r-1} \)

For the \( A_{r-1} \) case, the equilibrium position, \( \bar{q}_j \) the solution \( \{ \bar{q}_j \} \) of the \( A_{r-1} \) equation (2.83), is the same as the original Sutherland system (2.31). Therefore the polynomial describing the equilibrium is same as the original Sutherland system, the Chebyshev polynomial of the first kind \( T_r(x) \) (2.33). In other words the Chebyshev polynomials are not deformed in the present scheme.

5.2 \( B'C_r \)

\( B'C_r \) : For the solution \( \{ \bar{q}_j \} \) of the \( B'C_r \) equation (2.88), let us define

\[ \delta = \tanh^2 g_M, \quad \alpha = \frac{\tanh g_S}{\tanh g_M} + \frac{\tanh 2g_L}{2 \tanh g_M} - 1, \quad \beta = \frac{\tanh 2g_L}{2 \tanh g_M} - 1, \]

(5.1)
and introduce a degree $r$ polynomial in $x$ having zeros at $\{\cos 2\bar{q}_j\}$:

$$ P_r^{(\alpha,\beta)}(x, \delta) \overset{\text{def}}{=} 2^{-r} \left(\frac{\alpha+\beta+2r}{r}\right) \prod_{j=1}^{r} (x - \cos 2\bar{q}_j). $$  \hfill (5.2)

It is a deformation of the Jacobi polynomial \[2.33\] such that

$$ \lim_{\delta \to 0} P_r^{(\alpha,\beta)}(x, \delta) = P_r^{(\alpha,\beta)}(x). $$  \hfill (5.3)

The equation for the equilibrium \[2.38\] can be written as (we replace $r$ by $n$)

\[
\prod_{k=1}^{n} \frac{(1 + \frac{1}{\delta})(\cos 2\bar{q}_j + i \frac{2\sqrt{\delta}}{1 - \delta} \sin 2\bar{q}_j - \cos 2\bar{q}_k)}{(1 + \frac{1}{\delta})(\cos 2\bar{q}_j - i \frac{2\sqrt{\delta}}{1 - \delta} \sin 2\bar{q}_j - \cos 2\bar{q}_k)} = \sqrt{\delta} \cos 2\bar{q}_j + i \sin 2\bar{q}_j \left(\frac{\sin 2\bar{q}_j}{\cos 2\bar{q}_j} + i (\alpha - \beta)\sqrt{\delta}\frac{\sin 2\bar{q}_j}{\cos 2\bar{q}_j} + i 2(\beta + 1)\sqrt{\delta}\right),
\]

(5.4)

Since $\bar{q}_j$ can be restricted to $0 \leq \bar{q}_j \leq \pi/2$, $\sin 2\bar{q}_j$ is $\sin 2\bar{q}_j = \sqrt{1 - \cos^2 2\bar{q}_j}$. From this equation, for $-1 \leq x \leq 1$, we obtain the following functional equation for $P_n^{(\alpha,\beta)}(x, \delta)$ ($n \geq 1$),

\[
\left(\sqrt{\delta} x - i \sqrt{1 - x^2}\right) \left((\alpha - \beta)\sqrt{\delta}(1 + x) + i \sqrt{1 - x^2}\right) \left(2(\beta + 1)\sqrt{\delta} x + i \sqrt{1 - x^2}\right)
\times P_n^{(\alpha,\beta)}\left(\frac{1 + \frac{1}{\delta}}{1 - \frac{1}{\delta}} \sqrt{1 - x^2}, \delta\right)
- \left(\sqrt{\delta} x + i \sqrt{1 - x^2}\right) \left((\alpha - \beta)\sqrt{\delta}(1 + x) - i \sqrt{1 - x^2}\right) \left(2(\beta + 1)\sqrt{\delta} x - i \sqrt{1 - x^2}\right)
\times P_n^{(\alpha,\beta)}\left(\frac{1 + \frac{1}{\delta}}{1 - \frac{1}{\delta}} \sqrt{1 - x^2}, \delta\right)
= 2i \sqrt{1 - x^2} (A_n x^2 + B_n x + C_n) P_n^{(\alpha,\beta)}(x, \delta),
\]

(5.5)

because the LHS is $i \sqrt{1 - x^2}$ times a degree $n + 2$ polynomial in $x$ with real coefficients which vanishes at $x = \cos 2\bar{q}_j$. Here $A_n = A_n^{(\alpha,\beta)}(\delta)$, $B_n = B_n^{(\alpha,\beta)}(\delta)$ and $C_n = C_n^{(\alpha,\beta)}(\delta)$ are real constants:

\[
A_n = -(1 - \delta)^{-(n-1)} \times \frac{1}{2} \left((1 + (\alpha - \beta)\sqrt{\delta})(1 + 2(\beta + 1)\sqrt{\delta})(1 + \sqrt{\delta})^{2n-1}
+(1 - (\alpha - \beta)\sqrt{\delta})(1 - 2(\beta + 1)\sqrt{\delta})(1 - \sqrt{\delta})^{2n-1}\right),
\]

(5.6)

\[
B_n = -(\alpha - \beta)(1 + 2\beta)\delta,
\]

(5.7)

\[
C_n = (1 - \delta)^{-n} \times \frac{1}{2} \left((1 + (\alpha - \beta)\sqrt{\delta})(1 + 2(\beta + 1)\sqrt{\delta})(1 + \sqrt{\delta})^{2n-1}
+(1 - (\alpha - \beta)\sqrt{\delta})(1 - 2(\beta + 1)\sqrt{\delta})(1 - \sqrt{\delta})^{2n-1}
-2(\alpha - \beta - 1)(1 + 2\beta)\delta (1 - \delta)^{n-1}\right).
\]

(5.8)
The functional equation (5.5) contains all the information of the equilibrium. In the \( \delta \to 0 \) limit, this functional equation reduces to the differential equation of the Jacobi polynomial \( (2.104) \).

The three-term recurrence (2.90) for the deformed Jacobi polynomial \( P_n^{(\alpha, \beta)}(x, \delta) \) is a consequence of the functional equation (5.5) (see Appendix). The constants in (2.90) are

\[
a_n = (\beta - \alpha)(1 - \delta)^{n-1} \\
\times \frac{1}{2} \left( (1 + 2\beta) \left( (1 + (\alpha - \beta)\sqrt{\delta}) (1 + 2(\beta + 1)\sqrt{\delta}) (1 + \sqrt{\delta})^{2n-1} \\
+ (1 - (\alpha - \beta)\sqrt{\delta}) (1 - 2(\beta + 1)\sqrt{\delta}) (1 - \sqrt{\delta})^{2n-1} \right) \\
+ 2(\alpha - \beta - 1)(1 - 4(\beta + 1)^2 \delta) (1 - \delta)^{n-1} \right) \times \frac{1}{d_{2n} d_{2n+2}},
\]

\[
b_n = \frac{1}{2\sqrt{\delta}} \left( (1 + \sqrt{\delta})^n - (1 - \sqrt{\delta})^n \right) \\
\times \frac{1}{2} \left( (1 + 2(\beta + 1)\sqrt{\delta}) (1 + \sqrt{\delta})^{n-1} + (1 - 2(\beta + 1)\sqrt{\delta}) (1 - \sqrt{\delta})^{n-1} \right) \\
\times \frac{1}{2\sqrt{\delta}} \left( (1 + 2(\beta + 1)\sqrt{\delta}) (1 + \sqrt{\delta})^{2n-2} - (1 - 2(\beta + 1)\sqrt{\delta}) (1 - \sqrt{\delta})^{2n-2} \right) \\
\times \frac{1}{2\sqrt{\delta}} \left( (1 + (\alpha - \beta)\sqrt{\delta}) (1 + \sqrt{\delta})^{n-1} + (1 - (\alpha - \beta)\sqrt{\delta}) (1 - \sqrt{\delta})^{n-1} \right) \\
\times \frac{1}{2\sqrt{\delta}} \left( (1 + (\alpha - \beta)\sqrt{\delta})^2 (1 + 2(\beta + 1)\sqrt{\delta}) (1 + \sqrt{\delta})^{2n-2} \\
- (1 - (\alpha - \beta)\sqrt{\delta})^2 (1 - 2(\beta + 1)\sqrt{\delta}) (1 - \sqrt{\delta})^{2n-2} \right) \\
\times \frac{d_n}{d_{2n-1} d_{2n} d_{2n+1}}, \quad c_n = 2^{-n} (\frac{\alpha + \beta + 2n}{n}),
\]

\[
d_m = \frac{1}{2\sqrt{\delta}} \left( (1 + (\alpha - \beta)\sqrt{\delta}) (1 + 2(\beta + 1)\sqrt{\delta}) (1 + \sqrt{\delta})^{m-2} \\
- (1 - (\alpha - \beta)\sqrt{\delta}) (1 - 2(\beta + 1)\sqrt{\delta}) (1 - \sqrt{\delta})^{m-2} \right).
\]

Namely \( P_n^{(\alpha, \beta)}(x, \delta) \) satisfies

\[
\frac{2(n + 1)(\alpha + \beta + n + 1)}{(\alpha + \beta + 2n + 1)(\alpha + \beta + 2n + 2)} P_{n+1}^{(\alpha, \beta)}(x, \delta) + (x - a_n) P_n^{(\alpha, \beta)}(x, \delta) \\
+ \frac{\alpha + \beta + 2n - 1}{2n(\alpha + \beta + n)} b_n P_{n-1}^{(\alpha, \beta)}(x, \delta) = 0.
\]

In this case (5.1), the parameter ranges are \( \delta > 0 \) and \( \alpha > \beta > -1 \). So \( b_n \) is positive. From this three-term recurrence we obtain the difference equation for the generating function.
The functional equation of \(C\) and introduce a degree

It is a deformation of the Gegenbauer polynomial (2.35) such that

\[ G(x, \delta) = \sum_{n=0}^{\infty} t^n P_n^{(\alpha, \beta)}(x, \delta), \]

\[ \left( (d^2 \alpha - d^2 \beta) + (d^2 \alpha + d^2 \beta) \right) \left( \frac{\partial}{\partial t} + x \right) \left( d^2 \alpha - d^2 \beta \right) \right) G^{(\alpha, \beta)}(t, x, \delta) = 0. \]

It is interesting to note that the three-term recurrence (5.9)–(5.10) simplifies drastically in a ‘strong’ coupling limit,

\[ g_M \to +\infty \iff \delta \to 1, \quad g_L, g_S : \text{fixed}, \]

\[ a_0 = \frac{\beta - \alpha}{\alpha + \beta + 2}, \quad a_1 = \frac{(\beta - \alpha)(2\beta + 1)}{(\alpha + \beta + 2)(\alpha - \beta + 1)}, \quad a_n = 0, \quad (n \geq 2), \]

\[ b_1 = \frac{4(\beta + 1)(\alpha + 1 + (\beta + 1)(\alpha - \beta)^2)}{(\alpha - \beta + 1)(\alpha + \beta + 2)^2(2\beta + 3)}, \quad b_2 = \frac{\alpha + \beta + 2}{2(\alpha - \beta + 1)(2\beta + 3)}, \quad b_n = \frac{1}{4}, \quad (n \geq 3). \]

\(C_r\) : For the solution \(\{\bar{q}_j\}\) of the \(C_r\) equation (2.86), let us define

\[ \delta = \tanh^2 g_S, \quad \alpha = \frac{\tanh 2g_L}{2 \tanh g_S} - 1, \]

and introduce a degree \(r\) polynomial in \(x\) having zeros at \(\{\cos 2\bar{q}_j\}\) :

\[ C_r^{(\alpha + \frac{1}{2})}(x, \delta) \overset{\text{def}}{=} 2^r (\frac{\alpha - \frac{1}{2}}{r}) \prod_{j=1}^{r} (x - \cos 2\bar{q}_j). \]

It is a deformation of the Gegenbauer polynomial (2.35) such that

\[ \lim_{\delta \to 0} C_r^{(\alpha + \frac{1}{2})}(x, \delta) = C_r^{(\alpha + \frac{1}{2})}(x), \]

and obviously it is a special case of \(P_r^{(\alpha, \beta)}(x, \delta)\) with definite parity,

\[ C_r^{(\alpha + \frac{1}{2})}(x, \delta) = {2r \choose r} \left( \frac{\alpha + r}{\alpha} \right) \prod_{j=1}^{r} (x - \cos 2\bar{q}_j). \]

The functional equation of \(C_r^{(\alpha + \frac{1}{2})}(x, \delta)\) is easily obtained from that of \(P_r^{(\alpha, \beta)}(x, \delta)\) and will not be presented here. The three-term recurrence for \(C_n^{(\alpha + \frac{1}{2})}(x, \delta)\) reads

\[ \frac{n + 1}{2\alpha + 2n + 1} C_{n+1}^{(\alpha + \frac{1}{2})}(x, \delta) + x C_n^{(\alpha + \frac{1}{2})}(x, \delta) + \frac{2\alpha + 2n - 1}{n} \sum_{j=1}^{n} b_j C_{n-j}^{(\alpha + \frac{1}{2})}(x, \delta) = 0. \]
For the solution \( \{ \tilde{q}_j \} \) of the \( B'_r \) equation \((2.85)\), let us define

\[
\delta = \tanh^2 g_L, \quad \alpha = \frac{\tanh g_S}{\tanh g_L} - 1, \quad (5.22)
\]

and introduce a degree \( r \) polynomial in \( x \) having zeros at \( \{ \cos 2\tilde{q}_j \} \):

\[
\tilde{P}_r^{(\alpha)}(x, \delta) \overset{\text{def}}{=} 2^{-r}(\alpha^{1+2r}) \prod_{j=1}^{r} (x - \cos 2\tilde{q}_j). \quad (5.23)
\]

Obviously it is a special case of \( P_r^{(\alpha, \beta)}(x, \delta) \),

\[
\tilde{P}_r^{(\alpha)}(x, \delta) = P_r^{(\alpha, -1)}(x, \delta). \quad (5.24)
\]

The functional equation and three-term recurrence of \( \tilde{P}_n^{(\alpha)}(x, \delta) \) are obtained from those of \( P_n^{(\alpha, \beta)}(x, \delta) \).

### 5.3 \( C''_r \)

For the solution \( \{ \tilde{q}_j \} \) of the \( C'_r \) equation \((2.87)\), let us define

\[
\delta = \tanh^2 g_S, \quad \alpha = \frac{\tanh g_L}{\tanh g_S} - 1, \quad (5.25)
\]

and introduce a degree \( r \) polynomial in \( x \) having zeros at \( \{ \cos 2\tilde{q}_j \} \):

\[
\tilde{C}_r^{(\alpha+\frac{1}{2})}(x, \delta) \overset{\text{def}}{=} 2^{r}(\alpha^{1+2r}) \prod_{j=1}^{r} (x - \cos 2\tilde{q}_j). \quad (5.26)
\]

It is a deformation of the Gegenbauer polynomial \((2.35)\) with definite parity

\[
\lim_{\delta \to 0} \tilde{C}_r^{(\alpha+\frac{1}{2})}(x, \delta) = C_r^{(\alpha+\frac{1}{2})}(x), \quad \tilde{C}_r^{(\alpha+\frac{1}{2})}(-x, \delta) = (-1)^r \tilde{C}_r^{(\alpha+\frac{1}{2})}(x, \delta). \quad (5.27)
\]

The functional equation for \( \tilde{C}_n^{(\alpha+\frac{1}{2})}(x, \delta) \) \( (n \geq 1) \) reads

\[
(\sqrt{\delta} x - i\sqrt{1-x^2}) \left( (\alpha + 1)\sqrt{\delta} x + i\sqrt{1-x^2} \right)^2 \tilde{C}_n^{(\alpha+\frac{1}{2})}\left( \frac{1+i\sqrt{3}}{2} x + i\frac{2\sqrt{3}}{2} \sqrt{1-x^2}, \delta \right) - (\sqrt{\delta} x + i\sqrt{1-x^2}) \left( (\alpha + 1)\sqrt{\delta} x - i\sqrt{1-x^2} \right)^2 \tilde{C}_n^{(\alpha+\frac{1}{2})}\left( \frac{1-i\sqrt{3}}{2} x - i\frac{2\sqrt{3}}{2} \sqrt{1-x^2}, \delta \right) = 2i\sqrt{1-x^2} (A_n x^2 + B_n x + C_n) \tilde{C}_n^{(\alpha+\frac{1}{2})}(x, \delta). \quad (5.28)
\]

Here \( A_n = A_n^{(\alpha+\frac{1}{2})}(\delta) \), \( B_n = B_n^{(\alpha+\frac{1}{2})}(\delta) \) and \( C_n = C_n^{(\alpha+\frac{1}{2})}(\delta) \) are real constants:

\[
A_n = -(1 - \delta)^{-(n-1)} \times \frac{1}{2} \left( (1 + (\alpha + 1)\sqrt{\delta})^2(1 + \sqrt{\delta})^{2n-1}
\]

\[34\]
\[ + (1 - (\alpha + 1)\sqrt{\delta})^2 (1 - \sqrt{\delta})^{2n-1} \], \quad (5.29) \\
\]

\[ B_n = 0, \quad (5.30) \]

\[ C_n = (1 - \delta)^{-n} \times \frac{1}{2} (1 + (\alpha + 1)\sqrt{\delta})^2 (1 + \sqrt{\delta})^{2n-1} \\
+ (1 - (\alpha + 1)\sqrt{\delta})^2 (1 - \sqrt{\delta})^{2n-1} - 2\alpha^2\delta (1 - \delta)^{n-1}. \quad (5.31) \]

This functional equation contains all the information of the equilibrium.

The deformed Gegenbauer polynomial \( \tilde{C}_{n+\frac{1}{2}}(x, \delta) \) satisfies the three-term recurrence \((2.90)\) (see Appendix) with

\[ a_n = 0, \quad (5.32) \]

\[ b_n = \frac{1}{2\sqrt{\delta}} \left( (1 + \sqrt{\delta})^n - (1 - \sqrt{\delta})^n \right) \times \frac{d_n}{d_{2n-1}^2 d_{2n+1}}, \quad c_n = 2^n (\frac{\alpha}{n} - \frac{1}{n}), \quad (5.33) \]

\[ d_m = \frac{1}{2\sqrt{\delta}} \left( (1 + (\alpha + 1)\sqrt{\delta})^2 (1 + \sqrt{\delta})^{m-2} - (1 - (\alpha + 1)\sqrt{\delta})^2 (1 - \sqrt{\delta})^{m-2} \right). \quad (5.34) \]

Namely \( \tilde{C}_{n+\frac{1}{2}}(x, \delta) \) satisfies

\[ \sum_{m=0}^{\infty} t^m \tilde{C}_{n+\frac{1}{2}}(x, \delta) = 0. \quad (5.35) \]

In this case \((5.25)\), the parameters are \( \delta > 0 \) and \( \alpha > -1 \). So \( b_n \) is positive. From this three-term recurrence we obtain the difference equation for the generating function

\[ G^{\frac{1}{2}}(t, x, \delta) = \sum_{n=0}^{\infty} t^n \tilde{C}_{n+\frac{1}{2}}(x, \delta) \]

In a ‘strong’ coupling limit

\[ g_S \to +\infty \iff \delta \to 1, \quad g_L \text{ : fixed,} \quad (5.36) \]

the three-term recurrence \((5.33)-(5.34)\) simplifies drastically:

\[ b_1 = \frac{1}{(\alpha + 2)^2}, \quad b_2 = \frac{\alpha + 1}{(\alpha + 2)^2}, \quad b_n = \frac{1}{4}, \quad (n \geq 3). \quad (5.37) \]

5.4 \( B_r \)

\( B_r \) : For the solution \( \{\bar{q}_j\} \) of the \( B_r \) equation \((2.84)\), let us define

\[ \delta = \tanh^2 g_L, \quad \alpha = \frac{2 \tanh \frac{g_S}{2}}{\tanh g_L} - 1, \quad (5.38) \]
and introduce a degree \( r \) polynomial in \( x \) having zeros at \( \{ \cos 2\bar{q}_j \} \):

\[
\hat{P}_r^{(\alpha)}(x, \delta) \overset{\text{def}}{=} 2^{-\frac{r}{2}} (\alpha - 1 + 2r)^{\frac{r}{2}} \prod_{j=1}^{r} (x - \cos 2\bar{q}_j).
\]  

(5.39)

It is a deformation of the Jacobi polynomial (2.34) such that

\[
\lim_{\delta \to 0} \hat{P}_r^{(\alpha)}(x, \delta) = P_r^{(\alpha, -1)}(x).
\]  

(5.40)

The functional equation for \( \hat{P}_n^{(\alpha)}(x, \delta) \) \((n \geq 1)\) reads

\[
\begin{align*}
&\left( \sqrt{\delta} x - i\sqrt{1 - x^2} \right) \left( \frac{\alpha + 1}{2} \sqrt{\delta} (1 + x) + i\sqrt{1 - x^2} \right)^2 \hat{P}_n^{(\alpha)} \left( \frac{1 + \delta}{1 - \delta} x + i\sqrt{\frac{\alpha}{1 - \delta}} \sqrt{1 - x^2}, \delta \right) \\
&\quad - \left( \sqrt{\delta} x + i\sqrt{1 - x^2} \right) \left( \frac{\alpha + 1}{2} \sqrt{\delta} (1 + x) - i\sqrt{1 - x^2} \right)^2 \hat{P}_n^{(\alpha)} \left( \frac{1 + \delta}{1 - \delta} x - i\sqrt{\frac{\alpha}{1 - \delta}} \sqrt{1 - x^2}, \delta \right) \\
&\quad = 2i\sqrt{1 - x^2} (A_n x^2 + B_n x + C_n) \hat{P}_n^{(\alpha)}(x, \delta).
\end{align*}
\]  

(5.41)

Here \( A_n = A_n^{(\alpha)}(\delta) \), \( B_n = B_n^{(\alpha)}(\delta) \) and \( C_n = C_n^{(\alpha)}(\delta) \) are real constants:

\[
A_n = -(1 - \delta)^{-(n-1)} \times \frac{1}{2} \left( (1 + \frac{1}{2}(\alpha + 1) \sqrt{\delta})^2 (1 + \sqrt{\delta})^{2n-1} + (1 - \frac{1}{2}(\alpha + 1) \sqrt{\delta})^2 (1 - \sqrt{\delta})^{2n-1} \right),
\]  

(5.42)

\[
B_n = \frac{1}{2} (1 - \alpha^2) \delta,
\]  

(5.43)

\[
C_n = (1 - \delta)^{-n} \times \frac{1}{2} \left( (1 + \frac{1}{2}(\alpha + 1) \sqrt{\delta})^2 (1 + \sqrt{\delta})^{2n-1} + (1 - \frac{1}{2}(\alpha + 1) \sqrt{\delta})^2 (1 - \sqrt{\delta})^{2n-1} - (1 + \alpha^2 - \frac{1}{2}(\alpha + 1)^2 \delta \delta (1 - \delta)^{n-1}) \right).
\]  

(5.44)

This functional equation contains all the information of the equilibrium.

The deformed Jacobi polynomial \( \hat{P}_n^{(\alpha)}(x, \delta) \) satisfies the three-term recurrence (2.90) (see Appendix) with

\[
a_n = (1 - \alpha^2)(1 - \delta)^{n-1} \frac{d_n' d_{n+1}}{d_{2n} d_{2n+2}},
\]  

(5.45)

\[
b_n = 4 \frac{1}{2\sqrt{\delta}} \left( (1 + \sqrt{\delta})^{n-1} - (1 - \sqrt{\delta})^{n-1} \right) \times \frac{1}{2\sqrt{\delta}} \left( (1 + \sqrt{\delta})^n - (1 - \sqrt{\delta})^n \right)
\times \frac{d_n' d_{n+1}}{d_{2n-1} d_{2n+1}}, \quad c_n = 2^n (\alpha - 1 + 2n),
\]  

(5.46)

\[
d_m = \frac{1}{2\sqrt{\delta}} \left( (1 + \frac{1}{2}(\alpha + 1) \sqrt{\delta})^2 (1 + \sqrt{\delta})^{m-2} - (1 - \frac{1}{2}(\alpha + 1) \sqrt{\delta})^2 (1 - \sqrt{\delta})^{m-2} \right),
\]  

(5.47)

\[
d_m' = \frac{1}{2} \left( (1 + \frac{1}{2}(\alpha + 1) \sqrt{\delta}) (1 + \sqrt{\delta})^{m-1} + (1 - \frac{1}{2}(\alpha + 1) \sqrt{\delta}) (1 - \sqrt{\delta})^{m-1} \right).
\]  

(5.48)
Namely \( \hat{P}_n^{(\alpha)}(x, \delta) \) satisfies
\[
\frac{2(n+1)(\alpha+n)}{(\alpha+2n)(\alpha+2n+1)} \hat{P}_{n+1}^{(\alpha)}(x, \delta) + (x - a_n) \hat{P}_n^{(\alpha)}(x, \delta) + \frac{(\alpha + 2n - 2)(\alpha + 2n - 1)}{2n(\alpha + n - 1)} b_n \hat{P}_{n-1}^{(\alpha)}(x, \delta) = 0 ,
\]
(5.49)
In this case (5.38), the parameters are \( \delta > 0 \) and \( \alpha > -1 \). So \( b_n \) is positive. From this three-term recurrence we obtain the difference equation for the generating function \( G^{(\alpha)}(t, x, \delta) = \sum_{n=0}^{\infty} t^n \hat{P}_n^{(\alpha)}(x, \delta) \) in a similar way to that of \( P_n^{(\alpha, \beta)}(x, \delta) \).

In a ‘strong’ coupling limit
\[
g_L \to +\infty \iff \delta \to 1, \quad g_S : \text{fixed},
\]
(5.50)
the three-term recurrence (5.45)–(5.48) simplifies drastically:
\[
a_0 = -1, \quad a_1 = \frac{1 - \alpha}{\alpha + 3}, \quad a_n = 0, \quad (n \geq 2),
\]
(5.51)
\[
b_1 = 0, \quad b_2 = \frac{2(\alpha + 1)}{(\alpha + 3)^2}, \quad b_n = \frac{1}{4}, \quad (n \geq 3).
\]
(5.52)

\( D_r \): As in the Sutherland systems, the \( D_r \) is a special case \( g_S = 0 \) of the \( B_r \) theory described by \( \hat{P}_r^{(-1)}(x, \delta) \), which has a zero at \( x = \pm 1 \) for \( r \geq 2 \).

**Deformation of the identities :** Before closing this section let us briefly discuss the deformation of the identities between the Chebyshev and Jacobi polynomials (2.37)–(2.38) and those between the Jacobi polynomials (2.39). As remarked in section 5.1 the Chebyshev polynomials describing the equilibrium of the \( A_{r-1} \) systems are not deformed in our scheme. Therefore no deformation of the identities (2.37)–(2.38) exists. The folding \( D_{r+1} \to B_r \) (2.52) leads to the identity between the deformed Jacobi polynomials \( \hat{P}_r^{(\alpha)}(x, \delta) \) (5.39) associated with the \( B_r \) systems
\[
2(r+1)\hat{P}_{r+1}^{(-1)}(x, \delta) = r(x-1)\hat{P}_r^{(1)}(x, \delta) ,
\]
(5.53)
which is a deformation of the identity (2.39). As remarked at the end of section 2.1 we have not been able to deform the identities between the Gegenbauer and Jacobi polynomials (2.40)–(2.41) as they do not seem to have a root theoretic explanation.

Among the deformed Jacobi polynomials \( P_n^{(\alpha, \beta)}(x, \delta) \) for various \( \alpha \) and \( \beta \), two cases (i) \( \alpha = \beta = -1/2 \), (ii) \( \alpha = -\beta = 1/2 \) are not deformed:
\[
P_n^{(-1/2, -1/2)}(x, \delta) = P_n^{(-1/2, -1/2)}(x), \quad P_n^{(1/2, -1/2)}(x, \delta) = P_n^{(1/2, -1/2)}(x).
\]
(5.54)
The first is the Chebyshev polynomial of the first kind $T_n(x) \propto \cos n\varphi$, $x = \cos \varphi$, as remarked in section 5.1. The second case is $P_n^{(1/2,-1/2)}(x) \propto \sin((2n + 1)\varphi/2)/\sin(\varphi/2)$, $x = \cos \varphi$. In both cases, the zeros of $P_n^{(\alpha,\beta)}(x)$ are equally spaced. There is a third case of equally spaced zeros of the Jacobi polynomial $P_n^{(\alpha,\beta)}(x)$, for $\alpha = \beta = 1/2$, corresponding to the Chebyshev polynomial of the second kind $U_n(x) \propto \sin n\varphi/\sin \varphi$, $x = \cos \varphi$, which is, interestingly, deformed. We have no explanation to offer.

6 Summary and Comments

We have derived certain deformation of the classical orthogonal polynomials (the Hermite, Laguerre, Gegenbauer and Jacobi) describing the equilibrium of a class of multiparticle dynamics, the Ruijsenaars-Schneider systems. The R-S systems are ‘good’ deformation of the Calogero and Sutherland systems whose equilibrium points are described by the zeros of the above classical orthogonal polynomials. As remarked in the text these deformed polynomials do not belong to the $q$-deformed orthogonal polynomials [15] or their analogs [21].

The quality and quantity of the knowledge of these new polynomials are rather varied. The one parameter deformation of the Hermite polynomials section 3.1 is best understood. Its three-term recurrence (3.11) tells that it is the simplest possible deformation which reduces to the original Hermite polynomial without rescaling etc in the zero deformation limit ($\delta \to 0$). As shown in some detail in section 3.1 the generating function (3.14) and the weight function (3.21) are known explicitly. Some identities connecting the Hermite and Laguerre polynomials (2.20)–(2.21) are nicely deformed (4.46)–(4.47), (4.48)–(4.49). It is interesting to note that some non-trivial identities of the Hermite polynomials are preserved after deformation. For example, the ‘addition theorem’ reads

$$\sum_{n_1,\ldots,n_m=0}^{\infty} \frac{\alpha_1^{n_1} \cdots \alpha_m^{n_m}}{n_1! \cdots n_m!} H_{n_1}(x_1) \cdots H_{n_m}(x_m) = \frac{|\vec{\alpha}|^n}{n!} H_n\left(\frac{\vec{\alpha} \cdot \vec{x}}{|\vec{\alpha}|}\right),$$

(6.1)

in which the following notation is used: $\vec{\alpha} = \langle \alpha_1, \ldots, \alpha_m \rangle$, $\vec{x} = \langle x_1, \ldots, x_m \rangle$, $|\vec{\alpha}| = \sqrt{\alpha_1^2 + \cdots + \alpha_m^2}$, $\vec{\alpha} \cdot \vec{x} = \alpha_1 x_1 + \cdots + \alpha_m x_m$. The deformed version is

$$\sum_{n_1,\ldots,n_m=0}^{\infty} \frac{\alpha_1^{n_1} \cdots \alpha_m^{n_m}}{n_1! \cdots n_m!} H_{n_1}(x_1, \frac{\delta}{\alpha_1^2}) \cdots H_{n_m}(x_m, \frac{\delta}{\alpha_m^2}) = \frac{|\vec{\alpha}|^n}{n!} H_n\left(\frac{\vec{\alpha} \cdot \vec{x}}{|\vec{\alpha}|}, \frac{\delta}{|\vec{\alpha}|^2}\right),$$

(6.2)
Both can be derived from the generating functions.

After a long and laborious search through existing literature, we find out that all the deformed orthogonal polynomials introduced in the main text can be related to particular members of the Askey-scheme of hypergeometric orthogonal polynomials [16].

The deformed Hermite polynomial \( H_n(x, \delta) \) is related to the Meixner-Pollaczek polynomial \( P_n^{(\lambda)}(x; \phi) \) (§1.7 of [16]):

\[
H_n(x, \delta) = n! \sqrt{\delta}^n P_n^{(\lambda)} \left( \frac{x}{\sqrt{\delta}} ; \frac{\pi}{2} \right).
\]

This identification allows a simple expression of its general term in terms of a (truncated) hypergeometric series \( _2F_1 \):

\[
H_n(x, \delta) = 2^n n! \sqrt{\delta}^n \left( \frac{\delta}{2} \right)_n \phantom{} _2F_1 \left( \frac{-n, \frac{1}{\delta} + \frac{i}{\sqrt{\delta}}}{2} \right)
\]

\[
= 2^n n! \sum_{k=0}^{n} (-1)^k \binom{n}{k} \prod_{j=0}^{k-1} \left( ix + \frac{1}{\sqrt{\delta}} + \sqrt{\delta} j \right) \times \prod_{j=k}^{n-1} \left( 1 + \frac{\sqrt{\delta}}{2} j \right),
\]

which is deformation of (2.18). The two-parameter deformation of the Hermite polynomial \( H_n(x, \delta, \varepsilon) \) is a special case of the continuous Hahn polynomial (§1.4 of [16]):

\[
H_n(x, \delta, \varepsilon) = 2^n n! \sqrt{\delta}^n \left( \frac{\delta}{2} \right)_n \phantom{} _2F_1 \left( \frac{-n, \frac{1}{\delta}, \frac{1}{\delta} + \frac{1}{\delta \varepsilon}}{2} \right).
\]

The (two-parameter) deformed Laguerre polynomial \( L_n^{(\alpha)}(x, \gamma, \delta) \) is the continuous dual Hahn polynomial (§1.3 of [16]) with rescaling:

\[
L_n^{(\alpha)}(y^2, \gamma, \delta) = \delta^n \frac{S_n \left( \frac{y^2}{\delta} ; \frac{1}{\delta} + 1, \alpha_1 + 1, \alpha_2 + 1 \right)}{n!},
\]

in which \( \alpha_1 \) and \( \alpha_2 \) are the two roots of \( x^2 - (\alpha - 1)x + \gamma - \alpha = 0 \). The (three-parameter) deformed Laguerre polynomial \( L_n^{(\alpha)}(x, \gamma, \delta, \varepsilon) \) is the Wilson polynomial (§1.1 of [16]) with rescaling:

\[
L_n^{(\alpha)}(y^2, \gamma, \delta, \varepsilon) = \frac{\frac{\delta^n}{n!} \left( \frac{n + \alpha + \frac{1}{\delta} + \frac{1}{\delta \varepsilon}}{n + \alpha - 1} \right)_n \phantom{} _2F_1 \left( \frac{\frac{y^2}{\delta}}{\delta} ; \frac{\frac{1}{\delta}}{\delta \varepsilon} + 1, \alpha_1 + 1, \alpha_2 + 1 \right)}{n!}\]

The deformed Jacobi polynomial \( P_n^{(\alpha,\beta)}(x, \delta) \) is a special case of the Askey-Wilson polynomial (§3.1 of [16]):

\[
P_n^{(\alpha,\beta)}(x, \delta) = 2^{-n} \left( \frac{\alpha + \beta + 2n}{n} \right) (ab^2 q^{-n-1} ; q)_n^{-1} P_n(x ; a, b, -b, -1 | q),
\]

\[
q = \frac{1 - \sqrt{\delta}}{1 + \sqrt{\delta}} = e^{-2g_M}, \quad a = \frac{1 - (\alpha - \beta) \sqrt{\delta}}{1 + (\alpha - \beta) \sqrt{\delta}} = e^{-2g_L}, \quad b^2 = \frac{1 - 2(\beta + 1) \sqrt{\delta}}{1 + 2(\beta + 1) \sqrt{\delta}} = e^{-4g'}, (6.9)
\]

\[39\]
The deformed Gegenbauer polynomial $\tilde{C}_n^{(\alpha+\frac{1}{2})}(x, \delta)$ (5.26) is again a special case of the Askey-Wilson polynomial (§3.1 of [16]):

$$\tilde{C}_n^{(\alpha+\frac{1}{2})}(x, \delta) = (a^{2n} q^{-1}; q)_n^{-1} p_n(x; a, a, -a, -a | q),$$

$$q = \frac{1 - \sqrt{\delta}}{1 + \sqrt{\delta}} = e^{-2g_s}, \quad a^2 = \frac{1 - (\alpha + 1) \sqrt{\delta}}{1 + (\alpha + 1) \sqrt{\delta}} = e^{-2gL}.$$ (6.10)

Another deformation of the Jacobi polynomial $\hat{P}_n^{(\alpha)}(x, \delta) \text{ (5.39)}$ is also a special case of the Askey-Wilson polynomial (§3.1 of [16]):

$$\hat{P}_n^{(\alpha)}(x, \delta) = 2^{-2n} (a^{2n} q^{-1}; q)_n^{-1} p_n(x; a, a, -1, -1 | q),$$

$$q = \frac{1 - \sqrt{\delta}}{1 + \sqrt{\delta}} = e^{-2gL}, \quad a = \frac{1 - \frac{1}{2} (\alpha + 1) \sqrt{\delta}}{1 + \frac{1}{2} (\alpha + 1) \sqrt{\delta}} = e^{-gs}.$$ (6.12)

In all these formulas the Pochhammer symbol $(a)_k = \prod_{j=0}^{k-1} (a+j)$ and its $q$-extension $(a; q)_k = \prod_{j=0}^{k-1} (1 - aq^j)$ are used.

Various ‘strong’ coupling limits (5.14), (5.36) and (5.50) of the deformed Jacobi type polynomials $P_n^{(\alpha,\beta)}(x, \delta)$, $\tilde{C}_n^{(\alpha+\frac{1}{2})}(x, \delta)$ and $\hat{P}_n^{(\alpha)}(x, \delta)$ simply correspond to the ‘crystal’ limit $q \to 0+$ of the Askey-Wilson polynomials (6.8), (6.10) and (6.12).

For all these polynomials discussed in the present paper, the general term can be expressed in terms of various hypergeometric functions $2F_1$, $3F_2$, $4F_3$ and $4\phi_3$. A Rodrigue type formula, the generating function and the weight function etc can be written down by using the general formulas of the Askey-scheme of hypergeometric orthogonal polynomials [16].

As remarked repeatedly in the text, the equations determining the equilibrium positions, (2.60)–(2.64), (2.69)–(2.73) and (2.83)–(2.89) look similar to the Bethe ansatz equation. For the simplest spin 1/2 XXX chain with $N$ sites, the Bethe ansatz equation reads

$$\prod_{k=1, k \neq j}^{l} \frac{\bar{q}_j - \bar{q}_k + 2i}{\bar{q}_j - \bar{q}_k - 2i} = \left( \frac{\bar{q}_j + i}{\bar{q}_j - i} \right)^N, \quad (j = 1, \ldots, l),$$ (6.14)

in which $l \leq N$ is the number of up (down) spins. This looks similar to the rational $A$ type equations (2.60) and (2.69) with a special choice of the potential $w(x)$ function, the $N$-th power rather than linear or quadratic. The corresponding functional relation, Baxter’s $t$-$Q$ relation, looks very much like the functional equations (3.6) and (3.31). It would be interesting to pursue the analogy further.

Appendix: Relation between the Functional Equation and the Three Term Recurrence

In this appendix we show the relation between the functional equation and the three-term recurrence, without proof. Since the normalisation of polynomials is irrelevant, we consider monic polynomials $f_n(x)$ with real coefficients and without superscript ‘monic’.

The three-term recurrence of $f_n(x)$ (2.90) is

$$f_{n+1}(x) = (x - a_n)f_n(x) - b_n f_{n-1}(x), \quad (n \geq 0),$$  \hspace{1cm} (A.1)

with $f_{-1}(x) = 0$ and $f_0(x) = 1$. The explicit forms of $a_n$ and $b_n$ can be read from (3.10), (3.31), (4.5), (4.27), (5.5), (5.28), (5.41) and (5.41)².

The functional equations for the deformed Hermite, Laguerre and Jacobi polynomials have the following forms ($n \geq -1$):

Hermite : $h(x)f_n(x + i\sqrt{\delta}) + \epsilon h(x)^* f_n(x - i\sqrt{\delta}) = 2i\frac{\sqrt{\delta}}{1 - \delta} g_n(x) f_n(x)$, \hspace{1cm} (A.2)

Laguerre : $h(y)f_n[(y + i\sqrt{\delta})^2] + \epsilon h(y)^* f_n[(y - i\sqrt{\delta})^2] = 2i\frac{\sqrt{\delta}}{1 - \delta} g_n(y) f_n(y^2)$, \hspace{1cm} (A.3)

Jacobi : $h(x)f_n\left(\frac{1+i\delta}{1-\delta} x + i \frac{2\sqrt{\delta}}{1-\delta} \sqrt{1-x^2}\right) + \epsilon h(x)^* f_n\left(\frac{1+i\delta}{1-\delta} x - i \frac{2\sqrt{\delta}}{1-\delta} \sqrt{1-x^2}\right)
\hspace{1cm} = 2\left(i\sqrt{1-x^2}\right)^{\frac{1-\epsilon}{2}} g_n(x) f_n(x)$, \hspace{1cm} (A.4)

where $\epsilon$ is

$\epsilon = -1 : H_n(x, \delta), L_n^{(\alpha)}(x, \gamma, \delta), L_n^{(\beta)}(x, \delta), \tilde{L}_n^{(\alpha)}(x, \delta), \tilde{P}_n^{(\alpha,\beta)}(x, \delta), \tilde{C}_n^{(\alpha+\frac{1}{2})}(x, \delta), \tilde{P}_n^{(\alpha)}(x, \delta)$,

$\epsilon = 1 : H_n(x, \delta, \varepsilon), L_n^{(\alpha)}(x, \gamma, \delta, \varepsilon), L_n^{(\alpha)}(x, \delta, \varepsilon), \tilde{L}_n^{(\alpha)}(x, \delta, \varepsilon), \tilde{C}_n^{(\alpha+\frac{1}{2})}(x, \delta), \tilde{P}_n^{(\alpha)}(x, \delta)$.

The explicit forms of $h(x)$ and $g_n(x)$ can be read from [316], [331], [415], [427], [5.5], [5.28] and [5.41]².

As the first step, we show the following property of the functional equations:

²The explicit forms of the function $h(x)$ are derived from the equations for the equilibrium. For the
Proposition A.1 The solution of the functional equation (A.2)–(A.4), if exists, is unique up to an overall normalisation.

By this proposition, it is sufficient to construct one solution of each functional equation explicitly. We will do this by using the three-term recurrence.

As the second step, we show the following relation:

Proposition A.2 Three-term recurrence (A.1) implies the relation \( n \geq 0 \)\(^3\)

\[
\begin{align*}
\text{Hermite} : & \quad i^{\frac{1+\kappa}{2}} \sqrt{\delta} h(x) f_n(x + i\sqrt{\delta}) \\
& = \left((x - a_n)(g_{n+1}(x) - g_n(x)) + i\sqrt{\delta} g_n(x)\right) f_n(x) \\
& \quad - b_n \left(g_{n+1}(x) - g_{n-1}(x)\right) f_{n-1}(x), \quad \text{(A.5)} \\
\text{Laguerre} : & \quad 2i^{\frac{1+\kappa}{2}} \sqrt{\delta} y h(y) f_n\left((y + i\sqrt{\delta})^2\right) \\
& = \left((y^2 - a_n)(g_{n+1}(y) - g_n(y)) + \delta g_n(y) + 2i\sqrt{\delta} y g_n(y)\right) f_n(y^2) \\
& \quad - b_n \left(g_{n+1}(y) - g_{n-1}(y)\right) f_{n-1}(y^2), \quad \text{(A.6)} \\
\text{Jacobi} : & \quad \left(i\sqrt{1 - x^2}\right)^{\frac{1+\kappa}{2}} \frac{2\sqrt{\delta}}{1-\delta} h(x) f_n\left(\frac{1+\kappa}{1-\delta} x + i \frac{2\sqrt{\delta}}{1-\delta} \sqrt{1 - x^2}\right) \\
& = \left((x - a_n)g_{n+1}(x) - \left(\frac{1+\kappa}{1-\delta} x - a_n\right)g_n(x) + 2i\sqrt{1 - x^2} \frac{\sqrt{\delta}}{1-\delta} g_n(x)\right) f_n(x) \\
& \quad - b_n \left(g_{n+1}(x) - g_{n-1}(x)\right) f_{n-1}(x). \quad \text{(A.7)}
\end{align*}
\]

In the proof of this proposition by induction, we encounter the equation,

\[
X_n(x)f_n(x) - Y_n(x)b_n f_{n-1}(x) \overset{?}{=} 0 \quad \text{or} \quad X_n(y)f_n(y^2) - Y_n(y)b_n f_{n-1}(y^2) \overset{?}{=} 0. \quad \text{(A.8)}
\]

Here \( X_n(x) \) and \( Y_n(x) \) are as follows:

Hermite:

\[
\begin{align*}
X_n(x) & = (x - a_n)^2(g_{n+1}(x) - g_n(x)) - (x - a_n)(x - a_{n+1})(g_{n+2}(x) - g_{n+1}(x)) - \delta g_n(x) \\
& \quad - b_n(g_n(x) - g_{n-2}(x)) + b_{n+1}(g_{n+2}(x) - g_n(x)), \quad \text{(A.9)} \\
Y_n(x) & = (x - a_n)(g_{n+1}(x) - g_{n-1}(x)) - (x - a_{n-1})(g_{n-1}(x) - g_{n-2}(x)) \\
& \quad - (x - a_{n+1})(g_{n+2}(x) - g_{n+1}(x)), \quad \text{(A.10)}
\end{align*}
\]

deformed Hermite polynomials, \( g_n(x) \) are determined by the consistency of this functional equation. For the deformed Laguerre and Jacobi polynomials, however, \( g_n(x) \) are not determined uniquely by these functional equations. We have fixed \( g_n(x) \) by using some empirical knowledge of their lower degree members.

\(^3\)Although \( a_n \) vanishes for the deformed Hermite cases, we keep \( a_n \) in this generic formula.
Laguerre:

\[
X_n(y) = (y^2 - a_n - \delta)((y^2 - a_n)(g_{n+1}(y) - g_n(y)) + \delta g_n(y))
\]
\[
- (y^2 - a_n)((y^2 - a_{n+1})(g_{n+2}(y) - g_{n+1}(y)) + \delta g_{n+1}(y)) - 4\delta y^2 g_n(y)
\]
\[
-b_n(g_n(y) - g_{n-2}(y)) + b_{n+1}(g_{n+2}(y) - g_n(y)),
\]
\[
Y_n(y) = (y^2 - a_n - 2\delta)(g_{n+1}(y) - g_{n-1}(y)) - (y^2 - a_{n-1})(g_{n-1}(y) - g_{n-2}(y))
\]
\[
- (y^2 - a_{n+1})(g_{n+2}(y) - g_{n+1}(y)),
\]

Jacobi:

\[
X_n(x) = \left(\frac{1+\delta}{1-\delta}x - a_n\right)(x - a_n)g_{n+1}(x) - \left(\frac{1+\delta}{1-\delta}x - a_n\right)g_n(x)
\]
\[
- (x - a_n)((x - a_{n+1})g_{n+2}(x) - \left(\frac{1+\delta}{1-\delta}x - a_{n+1}\right)g_{n+1}(x)) - \left(\frac{2\sqrt{3}}{1-\delta}\right)^2(1 - x^2)g_n(x)
\]
\[
-b_n(g_n(x) - g_{n-2}(x)) + b_{n+1}(g_{n+2}(x) - g_n(x)),
\]
\[
Y_n(x) = \left(\frac{1+\delta}{1-\delta}x - a_n\right)(g_{n+1}(x) - g_{n-1}(x)) + (x - a_{n-1})g_{n-2}(x) - \left(\frac{1+\delta}{1-\delta}x - a_{n-1}\right)g_{n-1}(x)
\]
\[
- (x - a_{n+1})g_{n+2}(x) + \left(\frac{1+\delta}{1-\delta}x - a_{n+1}\right)g_{n+1}(x).
\]

It is easy to see \(X_n(x) = Y_n(x) = 0\) by using the explicit forms of \(a_n, b_n\) and \(g_n(x)\).

As the third step, we show the following:

**Proposition A.3** The polynomial defined by the three-term recurrence \((A.1)\) satisfies the functional equation \((A.2) - (A.4)\).

Therefore we obtain the following:

**Proposition A.4** The polynomial defined by the functional equation \((A.2) - (A.4)\) satisfies the three-term recurrence \((A.1)\).
