1. Introduction

Schiff bases and their derivatives have attracted considerable attention owing to their excellent synthetic flexibility, thermal stability, selectivity, and sensitivity towards the central metal atom.1–4 Schiff bases are considered as privileged ligands due to their excellent chelating abilities to furnish stable coordination complexes with a variety of metals, since they exhibit structural variations from N,N'-bidentate to N,N',X-tridentate and N,N',N,N'-tetra-dentate.5–7 Metal complexes ligated to Schiff base derivatives are endowed with a wide range of interesting properties appropriate for application in fields such as catalysis,9 medicine,10,11 crystal engineering12 as an anti-corrosion agent,13 photochemistry,14 biochemistry,15 organic synthesis,16 and materials science.17 More recently, transition metal complexes coordinated to the N-substituted N,N'- or N,N',N'-iminomethylpyridine derivatives proved to be promising candidates for selective catalysts18 and were successfully employed as ligands in various applications.19–21 For instance, Hsiao22 described the synthesis of Cu(n) complexes with iminopyridine ligands for atom transfer radical polymerization (ATRP). Similarly, iminomethylpyridine-based Fe(n) and Mo(0) complexes for the polymerization of MMA were reported to furnish syndio-enriched PMMA.23,24

Stereocontrol is of high importance during polymerization, as tacticity affects key mechanical properties of polymers, such as crystallinity, thermal behaviors and brittleness. Apart from mechanical properties, gas permeation and chemical degradation profile are also dependent on stereochemical makeup of polymer.25 However, careful choice of ligand architecture is mandatory to create stereo-controlled polymer. For instance, Marks and coworkers26 showed that chiral ansa-lanthanocenes give isotactic or syndiotactic PMMA based on the ligand assembly. Similarly, Yasuda and coworkers27 reported that Cp₂LnR (Ln = Sm or Yb) catalyzed highly syndiotactic PMMA. Schiff base derived late transition metal complexes, such as (z-diimine)-based nickel complexes, pyridylbisimine-based Fe(n) and Co(n), iminopyridine- or aminopyridine-based Fe(n) complexes polymerized MMA to give syndio-enriched PMMA.28 Schiff based derived-Zn(n) complexes displayed excellent catalytic performance with mediocre to high stereoselectivities.29,30 The design and synthesis of tridentate N,N',N''-Schiff bases ligands for controlled polymerization of polar monomers have been recently disclosed.31,32 In this regard, we have recently employed Pd(n), Zn(n), Cu(n) and Cd(n) initiators supported with iminomethylpyridine derived Schiff bases...
towards stereoselective ROP of rac-LA and MMA polymerization. These catalysts were effective and afforded high-molecular-weight PLAs and PMMAs with mediocre to high syndiotacticities.13–18 As an extension of our continuous interest in the stereoselective ROP of rac-LA and MMA polymerization, we synthesized Cu(n) complexes ligated to iminomethylpyridine derivatives and investigated their catalytic efficacy in MMA and rac-LA polymerization in this study.

2. Experimental

2.1. General considerations

All reactions were performed using standard Schlenk techniques under an atmosphere of high-purity argon or using glovebox techniques. All the starting materials including CuCl2·2H2O, 2-pyrindinecarboxaldehyde, N,N-dimethylethylene-diamine, 2-methoxyethylamine, 1-(2-aminooethyl)piperidine, 4-(2-aminooethyl) morpholine, 3-(dimethylamino)-1-propylamine, 3-methoxypropylamine, magnesium sulfate (MgSO4), molecular sieve (0.4 nm), methyl lithium solution (1.6 M in diethyl ether), and dichloromethane (CH2Cl2), ethanol (EtOH), dimethylformamide (DMF), diethyl ether were purchased from Aldrich and stored in a glove box. Toluene and THF were dried over CaH2 for 48 h, distilled under argon, and stored over activated molecular sieves (4 Å) and stirred at room temperature for 12 h to form a green powder. The solid was filtered and washed with cold EtOH (20.0 mL × 2), followed by washing with Et2O (20.0 mL × 3). The resultant solid was dried under vacuum to yield [LBECuCl2] as a final product (1.37 g, 92%). Analysis calculated for C15H19Cl2CuN3 (%): C, 44.4; H, 4.05; N, 9.38. Found: C, 36.0; H, 4.02; N, 9.19. FTIR (solid neat; cm−1): r(C–H) 2915 w; r(C–C) 1651 m; r(C≡N)/py and r(C≡C)py 1474 m and 1436 m; δ(C–H sp3) 1306 m; r(N–C) 1227 s; r(C–O) 1112 s; δ(C–H sp3) 837 m.

2.2. Synthesis

2.2.1. 2-Methoxy-N-(pyridin-2-ylmethylene)ethanamine(dichlorocopper)(n), [LCuCl2]2. A solution of L(0.821 g, 5.00 mmol) in anhydrous EtoH (10.0 mL) was added to a solution of CuCl2·2H2O (0.852 g, 5.00 mmol) in anhydrous EtoH (10.0 mL) and stirred at room temperature for 12 h to form a green powder. The solid was filtered and washed with cold EtoH (20.0 mL × 2), followed by washing with Et2O (20.0 mL × 3). The resultant solid was dried under vacuum to yield [LFCuCl2] as a final product (1.33 g, 82%). Analysis calculated for C16H15Cl2CuN2O (%): C, 48.8; H, 4.54; N, 12.4. Found: C, 44.4; H, 4.6; N, 12.4; r(C–H sp3) 1306 m; r(N–C) 1215 s; δ(C–H sp3) 860 m.

2.2.2. 2-(Piperidin-1-yl)-N-(pyridin-2-ylmethylene)ethanamine(dichlorocopper)(n), [LCuCl2]. An analogous method described for [L4CuCl2]2 was adopted for the synthesis of [LCuCl2], except utilizing LC (1.0 g, 5.00 mmol) and CuCl2·2H2O (0.852 g, 5.00 mmol) to get the final product (1.44 g, 82%). Analysis calculated for C15H19Cl2CuN3 (%): C, 44.4; H, 5.44; N, 12.0. Found: C, 44.6; H, 5.48; N, 11.9. FTIR (solid neat; cm−1): r(C–H) 2935 w; r(C–C) 1656 m; r(C≡N)/py and r(C≡C)py 1599 m and 1462 w; δ(C–H sp3) 1326 m; r(N–C) 1215 s; δ(C–H sp3) 860 m.

2.2.3. N,3-Dimethyl-N2-(pyridin-2-ylmethylene)propane-1,3-diamine(dichloro) copper(n), [LCuCl2]. An analogous method described for [L4CuCl2]2 was adopted for the synthesis of [LCuCl2], except utilizing L(0.956 g, 5.00 mmol) and CuCl2·2H2O (0.852 g, 5.00 mmol) to yield the final product (1.35 g, 93%). Analysis calculated for C14H14Cl2CuN2 (%): C, 40.6; H, 5.26; N, 12.9. Found: C, 40.7; H, 5.24; N, 12.9. FTIR (solid neat; cm−1): r(C–H) 2896 w; r(C–C) 1486 m; r(C≡N)/py and r(C≡C)py 1590 m and 1438 w; δ(C–H sp3) 1385 m; r(N–C) 1226 s; δ(C–H sp3) 855 m.

2.2.4. 3-Methoxy-N-(pyridin-2-ylmethylene)propan-1-amine(dichloro) copper(n), [LCuCl2]. An analogous method described for [L4CuCl2]2 was adopted for the synthesis of [LCuCl2], except utilizing L(0.871 g, 5.00 mmol) and CuCl2·2H2O (0.852 g, 5.00 mmol) to yield the final product (1.33 g, 85%). Analysis calculated for C10H14Cl2CuN2O (%): C, 38.4; H,
4.51; N, 8.96. Found: C, 38.7; H, 4.51; N, 8.98. FTIR (solid neat; cm⁻¹): ν(C–H) 3017 w; ν(C–C) 1647 s; ν(C=N)/py and ν(C=C)/py 1597 m and 1476 w; δ(C–H sp³) 1449 m; ν(N–C) 1221 s; ν(C–O) 1118 s; δ(C–H sp³) 871 m.

2.3. Crystal structure determination

An X-ray-quality single crystal was coated with paratone-N oil and the diffraction data were acquired at different temperatures and wavelengths. At 100(2) K, the X-ray diffraction data of [L₆Cu(μ-Cl)Cl₂] and [L₄CuCl₂] were collected using synchrotron radiation with λ = 0.63000 and 0.61000 Å, respectively. At 200(2) K, the X-ray diffraction data of [L₄CuCl₂] and [L₆CuCl₂] were collected using home machine X-ray source (λ = 0.71073 Å) and synchrotron radiation (λ = 0.610 Å), respectively. The synchrotron X-ray diffraction data were collected using a Rayonix MX225HS CCD area detector at 2D SMC with a silicon (111) double crystal monochromator (DCM) at the Pohang Accelerator Laboratory, South Korea. The PAL BL2D-SMDC Program was used for data collection (detector distance is 66 mm, omega scan; Δω = 1°, exposure time varies 0.1–1 s per frame depending on the size of crystals) and HKL3000sm (Ver. 7.03r) was used for cell refinement, reduction, and absorption correction. The home machine X-ray diffraction data was collected using Bruker a APEX-II detector and sealed Mo Kα X-ray source (λ = 0.71073) with graphite monochromator. The Bruker SMART was used for data collection and cell refinement. The data reduction and absorption correction was done using Bruker SAINT and Bruker SADABS program, respectively. Structures were solved by direct methods, and refined by full-matrix least-squares refinement using the SHELXL-2018 (ref. 51) computer program. The positions of all non-hydrogen atoms were refined with anisotropic displacement factors. All hydrogen atoms in [L₆Cu(μ-Cl)Cl₂], [L₄CuCl₂], and [L₄CuCl₂] were placed using a riding model, and their positions were constrained relative to their parent atoms using the appropriate HFIX command in SHELXL-2018. All hydrogen atoms in [L₄CuCl₂] were found in difference Fourier map and refined isotopically. X-ray crystallography with PLS-II 2D-SMC beamline was supported by MSIP and POSTECH. The crystallographic refinements and structural data of [L₆Cu(μ-Cl)Cl₂], [L₄CuCl₂], [L₄CuCl₂], and [L₄CuCl₂] are summarized in Table S1.†

2.4. Ring opening polymerization of rac-LA

In the polymerization of rac-LA using a dimethyl copper initiator, the active catalyst species were generated as follows. Under dry argon conditions, dried THF (7.35 mL) was added to a 100 mL Schlenk flask containing the complex ([L₆CuCl₂] (0.156 g, 0.50 mmol), [L₄Cu(μ-Cl)Cl₂] (0.149 g, 0.50 mmol), [L₄CuCl₂] (0.176 g, 0.50 mmol), [L₄CuCl₂] (0.177 g, 0.50 mmol), [L₄CuCl₂] (0.163 g, 0.50 mmol), and [L₄CuCl₂] (0.156 g, 0.50 mmol)), and stirred to dissolve the complex. To this solution, MeLi (1.00 mmol, 0.65 mL of a 1.6 M solution in Et₂O) was added dropwise to produce the dimethyl Cu(n) species. After stirring at room temperature for 2 h, the THF solution of the resulting dimethyl Cu(n) complex was used to catalyze the ROP of rac-LA. The general procedure for the polymerization reaction was as follows. A Schlenk flask (100 mL) was charged with rac-LA (0.901 g, 6.25 mmol) under argon atmosphere and 5.00 mL of dried CH₂Cl₂ was added. The polymerization was initiated by slow addition of the catalyst solution (1.0 mL, 0.0625 mmol) via a syringe under argon at 25 °C and −25 °C. The reaction mixture was stirred for the specified time and the polymerization reactions were quenched by using H₂O (1.0 mL) followed by the addition of n-hexane (2.0 mL) and the solvent was evaporated directly to give sticky polymeric material. The resultant polymeric residue was subjected to monomer conversion determination, which was monitored by integrating monomer versus polymer methine resonances in ¹H NMR spectrum. The precipitates collected from the bulk mixture were again dissolved with CH₂Cl₂, and sequentially precipitated into n-hexane. Solvents were decanted and the white solids were dried in vacuo followed by drying in a vacuum oven at 40 °C for 12 h. ¹H NMR (CDCl₃, 500 MHz) for the obtained polymer: δ 5.13–5.20 (m, 1H), 1.51–1.63 (m, 3H).

The addition of water for quenching is assumed to be resulted in MeOH chain ends, and Cu species being slightly soluble in n-hexane and CH₂Cl₂ will remain in solution which was decanted. However, the complete removal of Cu traces from polymer is not confirmed yet, and this pending issue will be investigated in future works.

2.5. MMA polymerization

MMA was purified by distillation before use. Under dry argon conditions, dried toluene (10.0 mL) was added to a 250 mL Schlenk flask containing the complex ([L₆CuCl₂] (4.68 mg, 15.0 µmol), [L₄Cu(μ-Cl)Cl₂] (4.48 mg, 15.0 µmol), [L₄CuCl₂] (5.28 mg, 15.0 µmol), [L₄CuCl₂] (5.31 mg, 15.0 µmol), [L₄CuCl₂] (4.89 mg, 15.0 µmol), and [L₄CuCl₂] (4.69 mg, 15.0 µmol)) and stirred to dissolve the catalyst. In this flask, MMAO (modified methylaluminoxane, 5.90 wt% in toluene, 3.80 mL, [MMAO]₀/[M(n) catalyst]₀ = 500) was added. After the mixture had been stirred for 20 min, MMA (5.00 mL, 47.11 mmol, [MMA]₀/[M(n) catalyst]₀ = 3100) was transferred to the mixture of catalyst and cocatalyst. The reaction flask was immersed in an oil bath at 60 °C and stirred for 2 h with maintained temperature. The resulting product was placed in a mixture of MeOH (500 mL) and HCl (5.00 mL) and stirred to remove the remaining cocatalyst. The polymer was filtered and washed with MeOH (100 mL × 3) to obtain PMMA, and it was vacuum-dried at 60 °C overnight to remove the solvent.

3. Results and discussion

3.1. Synthesis and properties

Iminomethylpyridine ligands are important building blocks and are known to coordinate easily to transition metals due to their versatile coordination behavior and fine tuning of their stereo-electronic properties. In order to study the effects of different ligand substitution patterns on the polymerization behavior, six substituted 2-iminomethylpyridine derivatives have been selected. For instance, the linker unit variation in L₆
and $L_{E}$ with an identical iminomethylpyridine framework has been selected to investigate the influence of linking alkyl chain of amine and imine moieties on catalytic activities. For comparison ligands, $L_{B}$ and $L_{F}$, with an ether arm on imine functionality has been selected, an alkyl chain with an oxygen at fourth or fifth position, respectively, to generate mixed ligand architecture with better $\delta$-donor and $\pi$-acceptor properties. To further extend the substituent influence on activity and stereoselectivity, the morpholine and piperidine imidines as close-ring substituents in $L_{C}$ and $L_{D}$ have been employed to generate more rigid ligand framework. These iminomethylpyridine ligands ($L_{n} = L_{A} - L_{E}$) used in the current study were synthesized as reported previously (Fig. 1).36-41

A series of new Cu(ii) complexes were furnished (in yield = 81–93%) by treating these ligands ($L_{n} = L_{A} - L_{E}$) with CuCl$_{2} \cdot 2$H$_{2}$O in a 1:1 molar ratio in EtOH. The resultant Cu(ii) complexes were stable in the air and were not affected by the atmospheric constituents and could be stored for months at room temperature. The FTIR spectra of the ligands and their corresponding Cu(ii) complexes were compared. The characteristic IR bands assigned to $sp^{3}$ $v$(C–H), $v$(C=N), aromatic $v$(C=C), and aromatic $v$(C–H) stretch can be observed at $\sim$3000 cm$^{-1}$, $\sim$1650 cm$^{-1}$, 1500 cm$^{-1}$ and $\sim$800 cm$^{-1}$, respectively. In addition, C–O stretch can be identified at 1100 cm$^{-1}$ in ligands containing an oxygen atom. The bands assigned to $v$(C=N) of the azomethine group and $v$(C=N)$_{py}$ shifted to higher wavenumber in the spectra of all complexes, indicating the possibility of back donation and the participation of nitrogen atoms in bonding.24,35 Elemental analysis for all complexes was consistent with the proposed structures in Scheme 1. All the synthesized Cu(ii) complexes were soluble in common organic solvents.

### 3.2. Molecular structures of Cu(ii) complexes

Single crystals of $[L_{A}Cu(μ-Cl)Cl]_{2}$ and $[L_{E}CuCl]_{2}$ were obtained using a MeOH/Et$_{2}$O system, $[L_{A}CuCl]_{2}$ was obtained by a DMF/Et$_{2}$O layer, and $[L_{E}CuCl]_{2}$ was obtained through the acetone/n-pentane solvent diffusion method. The ORTEP diagrams of the complexes; $[L_{A}Cu(μ-Cl)Cl]_{2}$, $[L_{C}CuCl]_{2}$, $[L_{E}CuCl]_{2}$, and $[L_{F}CuCl]_{2}$ are shown in Fig. 1(a–d) and the detailed bond lengths and angles of complexes are shown in Table S2.† The X-ray structures of $[L_{A}CuCl]_{2}$ and $[L_{B}CuCl]_{2}$ have been published previously.42-44 $[L_{A}Cu(μ-Cl)Cl]_{2}$, $[L_{C}CuCl]_{2}$ and $[L_{E}CuCl]_{2}$ were crystallized in a monoclinic crystal system with $P2_{1}/c$, $P2_{1}/c$, $P2_{1}/c$ space groups, respectively, and $[L_{E}CuCl]_{2}$ crystallized in triclinic crystal system with a $P1$ space group (Fig. 2).

The Cu–N(pyridine) and Cu–N(imine) bond lengths lie in the ranges of 2.032(2)–2.0652(1) Å and 1.967(5)–2.0449(1) Å, respectively, while the average Cu–Cl bond length are observed to be 2.3290 Å. These geometric parameters are within the acceptable range reported for Cu(ii) complexes.36 The characteristic N=C bond lengths of imine moiety are 1.278(3) Å ($[L_{A}Cu(μ-Cl)Cl]_{2}$), 1.269(7) Å ($[L_{B}CuCl]_{2}$), 1.2751(2) Å ($[L_{C}CuCl]_{2}$), and 1.2703(2) Å ($[L_{D}CuCl]_{2}$), and agreed well with the acceptable value.24 However, the Cu(1)–O(1) lengths of 4.380 Å ($[L_{A}Cu(μ-Cl)Cl]_{2}$) and 5.949 Å ($[L_{B}CuCl]_{2}$) were too long to be considered for a coordinative bond. $[L_{A}Cu(μ-Cl)Cl]_{2}$ has a dimeric structure with a chloro bridge as described previously.24

The N(2)–Cu(1)–N(1) and N(3)–Cu(1)–N(2) bond angles in $[L_{A}Cu(μ-Cl)Cl]_{2}$, $[L_{C}CuCl]_{2}$, $[L_{E}CuCl]_{2}$ and $[L_{F}CuCl]_{2}$ ranged

---

**Fig. 1** List of iminomethylpyridine ligands ($L_{n} = L_{A} - L_{E}$) employed in the complexation to Cu(ii) centre.
from 78.89(2)$^\circ$ to 82.08(2)$^\circ$ and were affected by the substitution of the five-membered chelate ring. The bond angle of $\text{N(3)}$–$\text{Cu(1)}$–$\text{N(2)}$ in $\text{[LCuCl}_2\text{]}$ that constituted the six-membered chelate ring were 92.36(5)$^\circ$, which is similar to the published $\text{[LCuBr}_2\text{]}$ angle of 92.24(10)$^\circ$. The planes of both the piperidine group and the Cu(II) coordination were nearly vertical, and the piperidine group has a stable chair structure.

The structural parameters of the five-coordinated complexes can be obtained using the two largest coupling angles. This $\tau_5$ value is proposed as a simple metric for evaluating

---

**Scheme 1** Synthesis of Cu(II) complexes supported by iminomethylpyridine ligands.

---

**Fig. 2** An ORTEP drawings of $\text{[L}_2\text{Cu[\mu-CI]Cl}_2\text{]}$ (1-a), $\text{[L}_2\text{CuCl}_2\text{]}$ (1-b), $\text{[L}_3\text{CuCl}_2\text{]}$ (1-c), and $\text{[L}_4\text{CuCl}_2\text{]}$ (1-d) with thermal ellipsoids at 50% probability. All hydrogen atoms have been omitted for clarity.
quantitatively the geometry of five-coordinated complexes.\textsuperscript{40-42} A comparison of the $\tau_5$ values of Cu(II) complexes is shown in Table 1. The coordination geometry around the metal center of the Cu(II) complexes is depicted as a distorted square pyramid geometry. In the case of dimeric $[\text{LnCuCl}_2]$ the two molecules each share one Cl atom, so the dimeric molecule has two bridged Cl groups. Thus, it has a slightly distorted square pyramidal geometry consisting of the two nitrogen atoms and three Cl atoms of the ligand.

3.3. rac-LA polymerization

Biodegradable polymers that can display properties that rival poly-olefins are seen as future high-demand materials for a wide range of applications. Efforts have been directed toward decoupling polymeric materials from fossil fuel feedstocks using biological sources\textsuperscript{63,64} to decrease the amount of plastic waste ending up in the environment. Our research focuses on the stereoselective ROP of rac-LA\textsuperscript{65,66} the efficacy of iminomethylpyridine based Cu(II) complexes to mediate polymerization of rac-LA and to focus on the role played by the auxiliary ligand on influencing catalytic efficiency, molecular weight, as well as stereoselectivity. The dimethyl derivatives $[\text{LnCuMe}_2]$ ($\text{Ln} = \text{La} - \text{Lp}$), generated in situ, were assessed towards rac-LA polymerization at two different temperatures, i.e., 25 and $-25 \, ^\circ\text{C}$. Representative polymerization results are summarized in Tables 2 and 3. All the complexes were able to effectively initiate polymerization at room temperature and afforded PLA with desirable molecular weights and slightly higher PDIs; the heterotacticities were somewhat inferior ($P_3$ values ranged from 0.52 to 0.68; Table 2). Completion of the reaction was confirmed by the absence of the monomer signal in the $^1\text{H}$ NMR spectrum. The experimental $M_n$ values (corrected using Mark–Houwink\textsuperscript{67,68} factor 0.58) were consistent with the theoretical values, suggesting polymerization at the single reaction site provided by these dimethyl Cu(II) complexes. Slightly higher PDIs of PLAs produced with $[\text{LnCuMe}_2]$ ($\text{Ln} = \text{La} - \text{Lp}$) might be the consequence of backbiting or transesterification side reactions, which results in the formation of macrocycles with a broad molecular weight distribution (PDIs).

It can be suggested that the ROP of rac-LA by these initiators is mediated \textit{via} a coordination insertion mechanism.\textsuperscript{69,70} In this mechanism, the pre-coordination of the LA molecule to the metal center is crucial for the subsequent ring-opening step.

### Table 1. Five-coordinate geometry indices for Cu(II) complexes and representative examples from the literature

| Complexes | Geometry | $\tau_5$ | Reference |
|-----------|----------|----------|-----------|

a Conditions: [initiator] = 0.0625 mmol; [rac-LA]/[initiator] = 100; 5.00 mL of CH2Cl2 as polymerization solvent; polymerization time = 2 h; temp. = −25 °C. b Monomer conversion (%) determined by 1H NMR spectroscopy. c Calculated from [molecular weight of rac-LA] × [rac-LA]/[initiator] × conversion%. d Determined by gel permeation chromatography (GPC) in THF, relative to polystyrene standard (corrected using the Mark-Houwink factor of 0.58). e Probability of heterotactic enchainment ($P_i$) were calculated on the basis of homonuclear decoupled 1H NMR spectra according to literature.

The alkyl group then acts as a nucleophile and opens the LA ring (Scheme S1†). Blank polymerizations (entry 1 in Table 2) were also performed in the presence of MeLi alone, where PLA was obtained slowly with negligible stereoselectivity. These results suggest a role of the Lewis metal center and the ligand architecture that offers better polymerization control and steers the stereoselectivity of the resultant polymer.

The microstructural analysis revealed dimethyl Cu(n) complexes in the current study yielded hetero-enriched PLAs. It is evident from the polymerization data that preference for heterotactic enchainment is lower at room temperature (Table 2). On the other hand, the complexes [LnCuMe2] (Ln = LA–Lp), were able to exhibit better heterotacticities and molecular weight control at −25 °C. For instance, an increase in the $P_i$ values up to 0.88 and slight decrease in PDIs are observed at lower temperatures (Table 3). A closer look at polymerization data revealed no regular tendency of heterotacticity; the stereoselectivity of PLA was not significantly affected by the structure of the ancillary ligands attached to the central metal atom during the polymerization process. These results showed that the heterotacticity is comparable with that of previously reported Cu(n) complexes, but monomer conversion is excellent at lower temperatures. Enhanced heterotacticity was found with these dimethyl Cu(n) initiators bearing the proper complexity of the substituents at the nitrogens of the imine moiety. Heterotactic PLA obtained with these dimethyl Cu(n) complexes proceed via chain end-control mechanism, as previously demonstrated by the Daresbourg group for Zn(n) complexes with Schiff bases.24 Currently, research is underway in our laboratory to fully explain the role of the ROP mechanism and catalyst system, and further research will be concentrated on this.

3.4. MMA polymerization studies

The catalytic competencies of the synthesized Cu(n) complexes were investigated for MMA polymerization in the presence of modified MMAO at 60 °C. The representative polymerization data is tabulated in Table 4. All the complexes effectively polymerized MMA and the resultant polymer was isolated as a white solid and was characterized by GPC in THF using polystyrene standards. All complexes yielded PMMA with a $T_g$ in the range 123–128 °C.

Appropriate ligand architecture plays a pivotal role in endowing a high degree of polymerization control. Generally, the presence of bulky substituents around the metal center negatively affects MMA activation, suggesting that steric bulk of substituents or rigidity of ligand backbone hampered the approach of the monomer to the metal center. For instance, [LnCuCl2] displayed a higher activity with a more flexible propylene backbone compared to [LnCuCl2] with the ethylene backbone, despite of having identical dimethyl amine substituents (Table 4, entries 3 and 7). However, [LnCuCl2] (1.80 ×
$10^4$ g PMMA per mol Cu h) and [$L_4$CuCl$_2$] ($1.95 \times 10^4$ g PMMA per mol Cu h), with relatively bulkier piperidine and morpholine substituents and ethylene backbone, displayed higher activities compared to [$L_4$CuCl$_2$] ($1.77 \times 10^4$ g PMMA per mol Cu h) in contrast to our previous reports where steric bulk decrease activities.\footnote{16} If rigidity or steric hindrance provided by the amine substituents were the only factor that steered the catalytic activity, then one would have expected increased activity with [$L_4$CuCl$_2$] bearing dimethyl substituents at the amine moiety, as it provides a more open space than [$L_4$CuCl$_2$] and [$L_3$CuCl$_2$] do, with close ring substituents, but it actually exhibits a lower activity. Thus, it is obvious that appropriate complexity of substituents at the amine nitrogen is crucial for improved activities.

Further, the orientation of the amine substituents relative to the $xy$ plane of the pyridine ring and the metal center also influence the activity towards MMA polymerization. [$L_4$CuCl$_2$] with the piperidine moiety and [$L_4$CuCl$_2$] with the morpholine moiety that are perpendicular and slightly twisted toward the $xy$ plane of the $N$-((pyridin-2-yl)methylene)amine-Cu moiety by 64.01° and 69.23° showed slightly lower steric hindrance and exhibited higher activities than [$L_4$CuCl$_2$] and [$L_3$CuCl$_2$] do, with close ring substituents, but it actually exhibits a lower activity. Thus, it is obvious that appropriate complexity of substituents at the amine nitrogen is crucial for improved activities.

Among the synthesized Cu[$n$] complexes, the $L_4$-bearing Cu[$n$] complex exhibited the highest catalytic activity ($1.98 \times 10^4$ g PMMA per mol Cu h) and resulted in PMMA with high molecular weight ($9.96 \times 10^5$ g mol$^{-1}$) compared to that of the rest of complexes under identical experimental conditions. In addition, it is worth noting that the solubility of complexes in polymerization media showed an impact on the polymerization activity in previous research. Thus, the lower activity of [$L_4$Cu(μ-Cl)]$_2$ and [$L_4$CuCl$_2$] can also be attributed to its lower solubility in reaction media.

In comparison with our previously reported Cu[$n$] initiator bearing N-methyl-N-((pyridin-2-yl)methyl)benzeneamine, the current system was inferior in terms of activities and stereoselectivities but furnished PMMA with high $T_g$ and comparable molecular weights.\footnote{22} 2-Iminomethylpyridine- and 2-iminoethylquinoline-based Zn[$n$] and Pd[$n$] complexes accomplished syndio-enriched PMMA polymerization with slightly higher activities, which can be attributed to better electrophilicities of Zn[$n$] and Pd[$n$] complexes.\footnote{31,33} Recently studied $N,N$-di(2-picolyl)cyclohexylamine- based Pd, Cu, Zn, and Cd complexes for MMA polymerization exhibited lower activities with slightly better syndiotacticities compared to our currently studied catalysts. Similarly, $N$-((2-furanyl)methyl)-$N$-(1-3,5-dimethyl-1H-pyrazolyl)methyl-$N$-(phenylmethyl)amines-Cu[$n$] system\footnote{74} yielded syndiotactic PMMA (rr = 0.78) with only 30% conversion, whereas Cu[$n$] complex of 2-(pyrazol-3-yl)6-(pyrazolato)pyridine and related ligand\footnote{73} polymerized MMA with moderate activity and syndiotacticity. Thus, the current catalytic systems proved to be effective in polymerizing MMA and furnished syndio-enriched PMMA with good polymerization control.

To further explore the effect of the ligand and Lewis metal center in the polymerization process, the MMA polymerization was conducted with MMAO alone. A negligible amount of low-molecular-weight PMMA was obtained with almost no stereoregularity. Similarly, no polymer was produced with the dichloro copper($n$) complex in the absence of MMAO. The obtained PMMA was syndiotactic with all complexes regardless of the substituents attached to the ligand architecture and coordination mode, whereas the syndiotacticity was higher than that of PMMA made only with the co-catalyst, MMAO. In this study, the syndiotacticity and PDI were not significantly affected by the substituents of ligands around the metal center (Table 4). The activities of the catalyst for MMA and rac-LA polymerization can thus be considered to be influenced by the steric and

\end{table}
4. Conclusions

In this work, a new series of Cu(II) complexes supported by 2-iminomethylpyridine ligands were synthesized and characterized by a variety of techniques such as FTIR, elemental analysis, and X-ray diffraction. Distorted square pyramidal geometries were adopted by all the complexes via coordinating to ligands in the bi- or tridentate coordination modes. On activation with MMAO, all the complexes displayed moderate activities compared to that of the starting material. [LnCuMe2] with a propylene linker unit between the imine and amine moieties, exhibited the highest catalytic activity (1.95 × 10^4 g PMMA per mol Cu h), yielding the high-molecular-weight PMMA. All the complexes furnished syndiotactic PMMA regardless of the coordination modes. The stereospecific and electronic properties of the substituents did not follow a regular trend for the activity and stereoselectivity.
