**ABSTRACT**

Ribonuclease P (RNase P), a ribonucleoprotein (RNP) complex required for tRNA maturation, comprises one essential RNA (RPR) and protein subunits (RPPs) numbering one in bacteria, and at least four in archaea and nine in eukarya. While the bacterial RPR is catalytically active *in vitro*, only select euryarchaeal and eukaryal RPRs are weakly active despite secondary structure similarity and conservation of nucleotide identity in their putative catalytic core. Such a decreased archaeal/eukaryal RPR function might imply that their cognate RPPs provide the functional groups that make up the active site. However, substrate-binding defects might mask the ability of some of these RPRs, such as that from the archaean *Methanocaldococcus jannaschii* (Mja), to catalyze precursor tRNA (ptRNA) processing. To test this hypothesis, we constructed a ptRNA-Mja RPR conjugate and found that indeed it self-cleaves efficiently ($k_{\text{obs}}$ 0.15 min$^{-1}$ at pH 5.5 and 55°C). Moreover, one pair of Mja RPPs (POP5-RPP30) enhanced $k_{\text{obs}}$ for the RPR-catalyzed self-processing by ~100-fold while the other pair (RPP21-RPP29) had no effect; both binary RPP complexes significantly reduced the monovalent and divalent ionic requirement. Our results suggest a common RNA-mediated catalytic mechanism in all RNase P and help uncover parallels in RNase P catalysis hidden by plurality in its subunit make-up.

**INTRODUCTION**

Ribonuclease P (RNase P) is an endoribonuclease responsible for the 5' maturation of tRNAs. It is a ribonucleoprotein (RNP) complex containing one essential RNA (RNase P RNA; RPR) in all three domains of life and a varying number of protein subunits (RNase P Protein; RPP): one in bacteria, and at least four and nine in archaea and eukarya, respectively (1–6). The bacterial RPR is catalytically active in the absence of its RPP under *in vitro* conditions that include a high concentration of Mg$^{2+}$ (or another suitable divalent metal ion) which is essential for catalysis (1). However, only a few representative archaenal and eukaryal RPRs are weakly active under various conditions tested *in vitro* (6–9). This result is surprising given the remarkable secondary structure similarity and conservation of nucleotide identity in the putative catalytic core in all RPRs and raises the possibility that not all RPRs are functionally equivalent (Figure 1A–C; 10). We investigate here a euryarchaeal RPR that was reported to be inactive when tested alone (7,8) and examine the basis for its inactivity and its cooperation with cognate RPPs during catalysis. Based on the conserved structural elements of the RPR, euryarchaeal RNase P is classified into types A and M (8). At the secondary structure level, type A RPRs resemble the ancestral bacterial RPRs while type M RPRs lack some of the structural elements implicated in substrate binding in bacterial RPRs (Figure 1A–C; 8,10,11). Consistent with this observation, only a few type A RPRs and none of the type M RPRs are catalytically active *in vitro* without their RPPs (7). In this study, we employ *Methanocaldococcus jannaschii* (Mja) RPR as a prototype for type M RPRs. Using a unimolecular enzyme-substrate conjugate expected to alleviate substrate-binding defects in Mja RPR, we establish that Mja RPR (in the absence of RPPs) supports cleavage in cis, thus reaffirming the RPR’s pivotal catalytic role.

If the RPR is the catalytic moiety in RNase P from all three domains of life, why do archaeal/eukaryal RNase P holoenzymes require multiple RPPs for function *in vivo* while bacterial RNase P employs a single RPP, which serves to normalize the binding affinity and rate of cleavage of different precursor tRNAs (ptRNAs) by the RPR (12–15)? Biochemical characterization of a partially purified archaenal RNase P holoenzyme demonstrated that the RPR is associated with at least four RPPs (POP5, RPP30,
RPP21 and RPP29), which have eukaryal homologs (2,3). We recently reconstituted *Pyrococcus furiosus* (*Pfu*; type A) RNase P *in vitro* in an effort to develop archaeal RNase P as an experimental surrogate for the more complex eukaryal counterpart (16). In this study, by examining the role of RPPs in aiding the self-processing of the type M RPR-ptRNA cis conjugate, we are beginning to uncover functional parallels between the archaeal RPPs and the sole bacterial RPP.

**MATERIALS AND METHODS**

**Cloning of RPRs and ptRNA-RPR cis conjugates**

Complete details are provided in the Supplementary Data.

**RNase P activity assays**

The hybrid RPR and cis conjugates were folded as follows: incubation at 50°C for 30 min in water followed by 37°C for 30 min in 50 mM Tris-acetate (pH 8) containing either 100 mM Mg(OAc)2 and 2.5 M NH4OAc (for *Pt*<sup>Tyr</sup>-S<sub>T</sub>-M RPR) or 10 mM Mg(OAc)2 and 800 mM NH4OAc (for *Pt*<sup>Tyr</sup>-S<sub>T</sub>-M, *Pt*<sup>Tyr</sup>-S<sub>D</sub>-S<sub>M</sub> and *Eco*-type M RPRs).

In the absence of RPPs, trans cleavage by the hybrid RPR or self-cleavage by the cis conjugates was initiated by addition of 500 mM Mg(OAc)2 (or the amounts indicated if the experiment was a titration analysis).

To ensure that *Pt*<sup>Tyr</sup>-S<sub>T</sub>-M RPR does not self-cleave during reconstitution with *Mja* RPPs, we used two different pre-incubation strategies that permit assembly without promoting significant cleavage (Table 1). In the first approach, 50 nM *Pt*<sup>Tyr</sup>-S<sub>T</sub>-M RPR was mixed with 250 nM of each binary complex in 50 mM MES (pH 5.1 at 55°C), 800 mM NH4OAc, and either 1 mM Mg(OAc)2 (for POP5-RPP30) or 10 mM Mg(OAc)2 (for RPP21-RPP29). In the second approach, which was necessary for the reaction performed in the presence of all four RPPs, 25 mM Ca<sup>2+</sup> replaced Mg<sup>2+</sup> in the pre-incubation step. In both instances, reactions were initiated by adding an equal volume of 50 mM MES (pH 5.1 at 55°C), 800 mM NH4OAc, and 200 mM Mg(OAc)2 (final [Mg<sup>2+</sup>] = 100 mM).

Unless stated otherwise, all assays involved incubation for a specified period at 55°C in a thermal cycler. Reactions were terminated by adding an equal volume of stop solution [10 M urea, 5 mM EDTA, 0.05% (w/v) xylene cyanol, 10% (v/v) phenol]; if the time of incubation was short (e.g. 5 s) to accommodate rapid cleavage, reactions were terminated by first immersing the reaction tubes in liquid nitrogen and subsequently adding stop solution.

**Kinetic analysis**

The substrate and product RNAs were separated on either 8% or 10% (w/v) polyacrylamide/7 M urea gels and visualized by PhosphorImaging (Molecular Dynamics). The extent of cleavage was quantitated using ImageQuant (Molecular Dynamics) software. To obtain the rate of product formation (*k*<sub>obs</sub>), the product formed at time *t* (*P<sub>*t*</sub>) was fitted to *P*<sub>*t*</sub> = *P*<sub>o</sub>(1 - e<sup>-kt</sup>) using Kaleidagraph software (Synergy). Background cleavage during the 20-min pre-incubation used for RNP assembly was typically less than 5% and corrected using *P*<sub>*t*</sub> = *P*<sub>o</sub> + (*P*<sub>∞</sub> - *P*<sub>o</sub>)(1 - e<sup>-kt</sup>), where *P*<sub>o</sub> refers to product formed at *t*<sub>o</sub> (i.e. the end of the pre-incubation). In the cis conjugate reactions, the maximum product formed varied from 25 to 95% depending on the catalytic entity tested and assay pH.

**Dependence of rate on assay pH**

The rate of product formation was determined at 55°C and various pH values: 5.1–6.3 for *Pt*<sup>Tyr</sup>-S<sub>T</sub>-M RPR, 4.65–5.1 for *Pt*<sup>Tyr</sup>-S<sub>T</sub>-M RPR + POP5-RPP30, and 5.4–7.1 for *Pt*<sup>Tyr</sup>-S<sub>T</sub>-S<sub>D</sub>-S<sub>M</sub> RPR; 50 mM ammonium acetate (pH <5) or MES (pH >5) or HEPES (>6.5) buffers were employed in these assays. At each pH, at least three replicates were performed to obtain the mean and standard deviation values.

**RESULTS**

**Archaeal type M RPR supports ptRNA processing independently of its cognate RPPs**

Under prolonged incubation at pH 6 in the presence of 0.2 M Mg<sup>2+</sup> and 0.8 M NH<sub>4</sub><sup>+</sup>, human RPR was recently demonstrated to process a ptRNA-based model substrate (*k*<sub>obs</sub> ~10<sup>-2</sup> min<sup>-1</sup>, the pseudo-first order rate constant under single-turnover conditions; 9). Subsequently, the *Cyanophora paradoxa* cyanelle RPR, which is part of an RNase P with high protein content, was also reported to exhibit ptRNA cleavage at pH 6, 0.1 M Mg<sup>2+</sup> and 0.1 M NH<sub>4</sub><sup>+</sup> (*k*<sub>obs</sub> ~10<sup>-2</sup> min<sup>-1</sup>; 17). However, when we examined if the euryarchaeal type M RPRs would be active under analogous assay conditions with *Escherichia coli* (Eco) ptRNA<sup>Tyr</sup> as the substrate, we observed no activity with the *Archaeoglobus fulgidus* (*Afu*) and *Mja* RPRs (data not shown). No ptRNA processing activity was evident even with a variety of other assay conditions tested (37–55°C; 0.1–0.4 M Mg<sup>2+</sup>, 0.8–3 M NH<sub>4</sub><sup>+</sup>, pH 6–7.5; and RPR concentrations up to 20 μM; data not shown). The failure of type M RPRs to catalyze ptRNA cleavage in trans contrasts with the human RPR and might reflect differences in their structures.

If the inability of *Afu* and *Mja* RPRs to catalyze ptRNA processing is due to the absence of specific RNA structural elements (e.g. P8, L15; Figure 1C) implicated in ptRNA processing, it is possible that the type M RPR active. Towards this objective, we constructed a bacterial-archaeal (type M) hybrid RPR based on three observations. First, biochemical studies delineated the presence of two independently folding modules in bacterial RPRs: a substrate-specificity (S) domain that has conserved nucleotides for recognition of the T stem-loop of the ptRNA; and a catalytic (C) domain which can (i) recognize the leader, acceptor stem, and the 3′ terminal CCA sequence, and (ii) cleave the ptRNA (18–24). Second, we recently demonstrated that in *Pfu* RPR (euryarchaeal type A), the C domain was capable of cleaving ptRNA in the presence of two of its cognate RPPs (16). Lastly, mitochondrion-encoded RPRs in jakobid flagellates (e.g. *Reclinomonas americana*) became active upon
fusion of their C domains with the S domain of Eco RPR (25). Therefore, guided in part by the recent high-resolution structures of bacterial RPRs (26,27) and prior biochemical studies in which similar hybrids were generated, we constructed a hybrid RPR with the S domain of Eco RPR fused to the putative C domain of Mja RPR (EcoS-MjaC RPR; Figure 1D and Supplementary Data). Indeed, EcoS-MjaC RPR accurately processes ptRNA Tyr (Figure 1E). Therefore, Mja RPR supports trans cleavage of ptRNA Tyr if its S domain, probably defective in substrate binding, is replaced with a bacterial S domain that does not suffer from this limitation.

Since the above experiment revealed that the Mja RPR’s inactivity is likely due to defects in ptRNA recognition/binding, we inquired if an enzyme-substrate (ES) covalent conjugate in which a ptRNA is covalently tethered to the Mja RPR would facilitate its processing. However, we did not observe any cis cleavage when we tested conjugates in which ptRNATyr was attached to the 3' end of either Afu or Mja RPR [with spacers of either 50 nts (Afu) or 25 nts (Mja) to the cleavage site; data not shown].

As there was precedence for bacterial and archaeal type A RPRs supporting cis cleavage of a ptRNA attached to the L15 loop (7,28), we made similar constructs with Mja RPR especially since L15 is likely to be part of the active site in bacterial RPR (Figure 2A; see Supplementary Data; 20,21,26,27). When we tested such conjugates with spacers of 0, 5 and 10 nts, only the latter two were cleaved. However, since the 10-nt-spacer conjugate also exhibited some mis-cleavage, only the 5-nt-spacer conjugate was characterized further. The accuracy of cleavage in ptRNA Tyr-S5-M RPR (abbreviated as ptTyr-S5-M RPR; Figure 2A) was confirmed by comparing the migration of the 5' leader with that of a size marker generated by partial digestion of 5' labeled ptTyr-S5-M RPR with RNase T1 (Figure 2B).
M RPR and pt Tyr-S3-
B
RPP30 (Figure 3).
Correlating the rate of product formation with the hydro-
chemical step being rate limiting is generally derived from
the optimal condition as 55
A slope of 0.95 in the pH range 5.1-6.3 (Figure 3A). As
expected for a first-order reaction, we found that the k
obs values at various ptTyr-S3-M RPR concentrations are
nearly identical.
The k
obs value of 0.15 min\(^{-1}\) at pH 5.5 and 55°C for
ptTyr-S3-M RPR compares favorably to 0.75 min\(^{-1}\) at
pH 5.5 and 50°C reported for ptAsp-S5-Eco RPR (31).
This parallel in k
obs values is striking given that the type
M RPR lacks the functional S domain present in Eco RPR.
Tethering of the substrate to the type M RPR appears to
have rendered the S domain less essential. Importantly, the similar k
obs values, despite the different
ptRNA substrates, sites of conjugation, and assay tem-
peratures used in the two studies, might reflect comparable
ptRNA cleavage potential for the C domains of bacterial
and archaeal RPRs.

Only a subset of Mja RPPs influences the k
obs of
ptTyr-S3-M RPR self-cleavage
To examine the contribution of Mja RPPs to ptTyr-S3-M
RPR catalysis, we cloned the genes encoding Mja POP5,
RPP21, RPP29 and RPP30 into vectors that allow T7
RNA polymerase-based overexpression in E. coli BL21(DE3) cells. Our previous studies on in vitro reconsti-
tuted Pfu RNase P revealed that the four RPPs function as
two binary complexes (POP5-RPP30 and RPP21-RPP29;
16); therefore, we co-overexpressed the Mja RPPs as
binary complexes in E. coli. By exploiting the high pl
values of Mja RPPs (see Supplementary Data), we were
able to purify the complexes to near homogeneity by
cation-exchange chromatography. Details of the cloning,
overexpression and purification of Mja RPPs will be
described elsewhere. Purified Mja RPPs when combined with
the Mja RPR generated a functional Mja RNase P
holoenzyme that exhibited multiple turnover (k
cat \sim 6-24 min\(^{-1}\)) at 55°C with Eco ptRNA\(^{Tyr}\) or
Synechocystis
ptRNA\(^{Gln}\) (32) as the substrate. A k
cat value of 34 min\(^{-1}\) was reported for cleavage of Bacillus subtilis
ptRNA\(^{Amp}\) at 50°C by partially purified native Mja RNase P (33).

Both Mja POP5-RPP30 and RPP21-RPP29 decrease the
centration of monovalent and divalent ions
required for cis cleavage of ptTyr-S3-M RPR; the Mg\(^{2+}\)
requirement decreases from 500 to 100 mM with either
binary complex and decreases further to 20 mM with
both (Figure 4A; Table 1). In addition, Mja POP5-
RPP30, but not RPP21-RPP29, enhances by 100-fold the
maximal k
obs for self-processing of ptTyr-S3-M RPR at pH
5.1 and 55°C (0.05 to 4.8 min\(^{-1}\); Table 1). A plot of log

![Figure 3. Dependence of k\textsubscript{obs} on assay pH for self-cleavage of ptTyr-S5-
M RPR and ptTyr-S3-AS M RPR (A) and ptTyr-S5-M RPR + POP5-
RPP30 (B).](https://academic.oup.com/nar/article-abstract/36/12/4172/1140050/figure-3)
(k_{obs}) versus pH for the pt^{Tyr-S3-M} RPR + POP5-RPP30 exhibited a slope of 0.92 (Figure 3B). Slopes close to unity in plots of log(k_{obs}) versus pH for the self-cleavage of pt^{Tyr-S3-M} RPR with and without POP5-RPP30 indicate that the chemical step is rate limiting in both instances.

We next determined whether all four RPPs together will enhance k_{obs} to a level greater than that observed with just POP5-RPP30. However, technical issues prevented us from doing this experiment under conditions employed for the binary complexes. For reactions involving the RPR reconstituted with RPPs, we typically employ a pre-incubation step (10 min at 37°C followed by 10 min at 55°C) in a Mg^{2+}-containing buffer to permit RNP assembly prior to substrate addition (16). Since such an approach with the cis conjugate and four RPPs triggers significant self-cleavage during the pre-incubation step, we devised an alternative strategy.

As kinetic and thermodynamic studies using bacterial RPRs and ptRNAs revealed that the RPR adopts the correct tertiary fold for optimal ES complex formation with Ca^{2+}, a divalent cation that promotes efficient ptRNA binding but not processing (30), we pre-incubated pt^{Tyr-S3-M} RPR either with all four RPPs or just POP5-RPP30 in a buffer containing 25 mM Ca^{2+} instead of Mg^{2+}; cleavage was then initiated by adding an excess of Mg^{2+} to displace the Ca^{2+}. To estimate the concentration of Mg^{2+} required for displacing the Ca^{2+} and promoting maximal cleavage, the rate of self-processing was determined with a Mg^{2+}-titration analysis from 10 to 150 mM Mg^{2+}, which revealed that 100 mM Mg^{2+} is optimal.

Despite the viability of the above approach, it is conceivable that the calculated rate is influenced adversely by the pre-incubation with Ca^{2+} and its subsequent displacement by Mg^{2+}. Therefore, we compared the k_{obs} for self-processing of pt^{Tyr-S3-M} RPR + POP5-RPP30 under two conditions: assembled in a pre-incubation buffer containing either 1 mM Mg^{2+} or 25 mM Ca^{2+} and subsequently assayed in the presence of 100 mM Mg^{2+}. In both cases, the result was similar (4.8 versus 5.2 min^{-1}), thus validating the Ca^{2+}-based approach. Using this method, we determined that the k_{obs} for pt^{Tyr-S3-M} RPR self-cleavage with just POP5-RPP30 (5.2 min^{-1}) was not appreciably enhanced by addition of RPP21-RPP29 (5.5 min^{-1}; Table 1).

In the studies described above, due to technical issues thwarting the use of a rapid quench flow apparatus to perform transient kinetic assays at near-neutral pH and 55°C, we used an assay pH of 5.1 to enable manual determination for the rate of self-cleavage of pt^{Tyr-S3-M} RPR.

### Table 1. Effect of Mja RPPs on the ionic requirements and rate of self-processing of pt^{Tyr-S3-M} and pt^{Tyr-S3-ΔS-M} RPR conjugates at pH 5.1 and 55°C

| RNase P assayed | k_{obs}, min^{-1} | [NH_4]^+, M | [Mg^{2+}], M |
|----------------|------------------|-------------|-------------|
| Reconstituted and pre-incubated with low [Mg^{2+}] | | | |
| pt^{Tyr-S3-M} RPR | 0.05±0.01 | 2.5 | 0.5 |
| + RPP21-RPP29 | 0.06±0.01 | 0.8 | 0.1 |
| + POP5-RPP30 | 4.83±0.02 | 0.8 | 0.1 |
| Reconstituted and pre-incubated with Ca^{2+} | | | |
| pt^{Tyr-S3-M} RPR | 5.16±0.08 | 0.8 | 0.1 |
| + POP5-RPP30 | 5.46±0.04 | 0.8 | 0.1 |

*Rate at pH 5.1 obtained by extrapolating from values obtained between pH 5.4 and 7.1 (Fig. 3A).
cleavage scenario with the C domain of instead of the 25 000-fold defect observed in the trans (35), cleavage of pt Tyr-S3-
of thepared to the cis cleavage reaction used here. The activity S domain has a more adverse impact on the trans com-
slower than pt Tyr-S3-M RPR at pH 5.1 (0.004 versus
0.05 min
rate of pt Tyr-S3-
in high-resolution structural studies.

Indeed, ptTyr-S3-
conjugate should be active even without the S domain
since the substrate is covalently tethered to the enzyme. Therefore, the C domains of all RPRs, even those bereft of
the functionally important L15 and the neighboring P16/
P17 helices present in the bacterial RPR (9). The Mja ΔS RPR in ptTyr-S3-ΔS M RPR also represents the smallest functional RPR yet identified (135 nts) and could be used in high-resolution structural studies.

We examined the effect of RPPs on the self-cleavage rate of ptTyr-S3-ΔS M RPR. Addition of POP5-RPP30 resulted in a \( k_{\text{obs}} \) value of 4.9 min
−1, similar to 5.2 min
−1 observed with the wild type and indicates that this binary complex can compensate for the missing S domain. In contrast, addition of RPP21-RPP29 to ptTyr-S3-ΔS M RPR impacts neither the rate nor the ionic requirement. This finding suggests that RPP21-RPP29 asserts its effect on the RPR by binding to the S domain, a claim confirmed by our ongoing footprinting analysis which indicates that RPP21-RPP29 binds to the S domain (unpublished observations).

DISCUSSION

RPR is the catalytic subunit of RNase P in all three domains of life

Although the bacterial RPR alone is catalytically active under in vitro conditions of high ionic strength, until recently RPRs from many archaeal and all eukaryal sources were reported as incapable of catalysis without their cognate RPPs. These archaeal and eukaryal RPRs were not rendered active even in the presence of high concentrations of monovalent and divalent cations, which occasionally mitigate structural defects that prevent generation of an active RNA tertiary fold (6-8,36,37). The decreased activity in these RPRs might reflect a natural course towards a more complex RNP in which protein subunits provide functional groups that make up the active site. However, results from a recent study and the data reported here do not support such a premise. First, Kikovska et al. (9) showed that the human RPR can process different ptRNAs and model substrates, albeit 104-fold slower than that of bacterial RPR. Second, we have demonstrated here through engineering strategies intended to overcome substrate-binding defects that a euryarchaeal type M RPR, thus far found to be incapable of ptRNA processing, can catalyze this reaction (Figures 1 and 2).

Since the human and Mja (archaeal type M) RPRs can support ptRNA processing in the absence of RPPs when 150–500 mM Mg2+ is provided, it is evident that they possess the crucial structural elements required for generating the active site. These findings together with the fact that all characterized RPPs, either individually or in combination, cannot promote ptRNA processing without their RPRs confirm that the RPR is the catalytic moiety in all three domains of life. While such a broad inference might seem inconsistent with reports of failure to detect archaeal/eukaryal RPR-alone-catalyzed ptRNA processing, these results might reflect either an inability to form an active RPR fold in vitro or a masking of the cleavage capability due to extremely weak ptRNA binding (37).

Cleavage by Mja RPR is significantly enhanced by POP5-RPP30 at lower Mg2+ concentrations

Addition of the sole bacterial RPP normalizes the binding affinity and rate of cleavage of different ptRNAs by the cognate RPR; moreover, it enhances the affinity for Mg2+ ions in the active site thereby making a vital contribution to rate enhancement at physiological Mg2+ concentrations (14,15). What then are the roles played by the multiple archaeal/eukaryal RPPs?

Our studies on Pfu RNase P, where we examined the trans cleavage of a ptRNA under multiple turnover conditions, revealed that POP5-RPP30 (but not RPP21-RPP29) enhances the \( k_{\text{cat}} \) of the RPR by nearly 40-fold, in fact to the same extent observed with all four RPPs (16). This finding indicated that POP5-RPP30 plays a vital role in cleavage and/or product release. Although a comprehensive description of the kinetic scheme requires determining the rate constants for individual steps, we rationalized that studying the Mja RPR cis conjugate in the absence and presence of its cognate RPPs might permit us to focus on the chemical step (akin to a single-turnover reaction) without influence from substrate binding or product release. Even for a cis conjugate, however, \( k_{\text{obs}} \) (the apparent rate of product formation) need not be the rate of the chemical step as steps prior to cleavage could be rate limiting (see scheme below).

The maximal \( k_{\text{obs}} \) for self-cleavage of ptTyr-S3-M RPR is accelerated ~100-fold by Mja POP5-RPP30 but not at all by RPP21-RPP29 (Table 1). Similarly, only POP5-RPP30 promotes the trans cleavage of ptRNA by Mja RPR under multiple turnover conditions (unpublished observations). These findings are also consistent with our earlier observation that Pfu RPP21-RPP29 leaves the \( k_{\text{cat}} \) of the Pfu RPR-catalyzed reaction unaltered while decreasing the \( K_m \) five-fold and lowering the Mg2+ requirement (16).

We interpret our current results within a framework based on the kinetic scheme put forth by Harris and coworkers for trans cleavage of ptRNAs by Eco RNase
and 3). The maximal $k_{\text{obs}}$ determined for this reaction is similar to that observed for the RPR-alone reaction in the presence of its optimal $\text{Mg}^{2+}$ concentration of 500 mM (0.06 versus 0.05 min$^{-1}$; Table 1). Therefore, RPP21-RPP29 enables the RPR to attain its maximal $k_{\text{obs}}$ at a lower $\text{Mg}^{2+}$ concentration perhaps by enhancing the affinity of the RNP for $\text{Mg}^{2+}$ without affecting ES$^*$. If these RPPs and $\text{Mg}^{2+}$ bind to the folded state of the RPR, their binding will be thermodynamically coupled.

Since the \textit{Mja} RPR does not exhibit trans cleavage, we used the rate of self-processing of a cis conjugate as the baseline for its catalytic potential and then determined how RPPs influenced this rate. In the cis construct, the substrate is docked on the enzyme though likely not optimally positioned. If RPP21-RPP29 plays a role in substrate binding, its effect on the catalytic efficiency of a trans cleavage reaction might be more pronounced than in a cis reaction where the substrate is already docked. In fact, RPP21-RPP29 enhances by two fold the $k_{\text{obs}}$ for self-cleavage of a cis conjugate with a 5-nt spacer in contrast to a 3-nt-spacer construct where it has no effect (Table 1; data not shown). We are investigating if the pattern of activation by RPPs differs between a cis and a trans cleavage reaction.

The C domain of type M RPR is sufficient for processing a ptRNA provided in cis

Despite the identification of a conserved C domain in all RPRs, previous studies suggested that this domain by itself was either not functional in the absence of cognate RPPs or that its activity was nearly 25 000-fold weaker than the wild type (22,34,35). If this defect is attributable to weak substrate binding, covalent attachment of the substrate should remedy it. Indeed, our study shows that self-cleavage of pt$^{\text{Tyr-S}3\text{-M}}$ RPR is only 12-fold slower than pt$^{\text{Tyr-S}3\text{-M}}$ RPR at pH 5.1 (Table 1); moreover, the decreased activity suggests that the S domain does play a role in cleavage even in the cis conjugate (perhaps, by influencing $K_{\text{conf}}$). Such a function of the S domain is evident from the similarities in the functioning of bacterial and archaeal RPPs (35) and once again reveals parallels between the bacterial RPR’s C domain by its RPP (35) and once again reveals similarities in the functioning of bacterial and archaeal RNase P.

SUPPLEMENTARY DATA

Supplementary Data are available at NAR Online.

ACKNOWLEDGEMENTS

We are grateful to members of the Gopalan laboratory for useful suggestions and reagents during the course of this investigation, especially to Dr Lien Lai for her advice on cloning strategies and invaluable critique that improved the manuscript. We are indebted to Dr Mark Foster (OSU) for his insightful and important comments on the interpretation of kinetic data. We thank Dr Tim Eubank...
