THE SPECTRA OF VOLUME AND DETERMINANT DENSITIES OF LINKS

STEPHAN D. BURTON

Abstract. The volume density of a hyperbolic link $K$ is defined to be the ratio of the hyperbolic volume of $K$ to the crossing number of $K$. We show that there are sequences of non-alternating links with volume density approaching $v_{oct}$, where $v_{oct}$ is the volume of the ideal hyperbolic octahedron. We show that the set of volume densities is dense in $[0, v_{oct}]$. The determinant density of a link $K$ is $2\pi \log \det(K)/c(K)$. We prove that the closure of the set of determinant densities contains the set $[0, v_{oct}]$.

1. Introduction

Recent work in knot theory has studied the relationship between the hyperbolic volume of a knot or link and invariants of a knot or link that can be read from a diagram. See for example [8], [9], [10], [11], [13], and references therein. Recent work of Champanerkar, Kofman, and Purcell ([4], [5], and [6]) investigated a relationship between the volume of a knot, its determinant, and its crossing number. In this paper we continue to explore this relationship. We begin with the following invariant.

Definition 1.1. Given a hyperbolic link $K$, let $\text{vol}(K)$ be its hyperbolic volume, and let $c(K)$ be the crossing number of $K$. The volume density of $K$ is defined to be $d_{\text{vol}}(K) := \frac{\text{vol}(K)}{c(K)}$.

D. Thurston [16] showed that $d_{\text{vol}}(K) \leq v_{oct}$ for all knots $K$, where $v_{oct} \approx 3.66286$ is the volume of the regular ideal hyperbolic octahedron. This was done by decomposing $S^3 \setminus K$ into octahedra, placing one octahedron at each crossing, and pulling the remaining vertices to $\pm \infty$. Adams [1] showed that $\text{vol}(K) \leq (c(K) - 5)v_{oct} + 4v_{tet}$ for any link having $c(K) \geq 5$, where $v_{tet} \approx 1.01494$ is the volume of the ideal hyperbolic tetrahedron. Therefore $v_{oct}$ is a strict upper bound for the volume density of any finite link.

Champanerkar, Kofman, and Purcell [5] showed that the upper bound of $v_{oct}$ on volume density is asymptotically sharp. More precisely, there exist sequences of links $\{K_n\}_{n=0}^\infty$ such that $\lim_{n \to \infty} d_{\text{vol}}(K_n) = v_{oct}$ (see Theorem 2.3). Such sequences of links are called geometrically maximal. The authors of [3] produce examples of geometrically maximal sequences of links by constructing links approaching the infinite weave $W$, the infinite alternating link with the square lattice projection depicted in Figure 1.1. All the links in the examples constructed were alternating, and do not contain a cycle of tangles (see Definition 2.2). The first purpose of this paper is to show that there exist geometrically maximal sequences of links having a cycle of tangles (see Theorem 3.1). We then use this to prove Theorem 3.3 which states that there exist geometrically maximal sequences of non-alternating links.

Let $\mathcal{C}_{\text{vol}} = \{\text{vol}(K)/c(K) : K$ is a hyperbolic link$\} \subseteq \mathbb{R}$ and let $\text{Spec}_{\text{vol}}$ be the set of limit points of $\mathcal{C}_{\text{vol}}$. We call $\text{Spec}_{\text{vol}}$ the spectrum of volume densities. A question that arose in [5] was how one may describe the sets $\mathcal{C}_{\text{vol}}$ and $\text{Spec}_{\text{vol}}$. (See also [4] for discussion and related questions.) In particular,
what numbers occur as volume densities? Since \( v_{\text{oct}} \) forms an upper bound on volume density, it is clear that \( C_{\text{vol}} \) and \( \text{Spec}_{\text{vol}} \) are subsets of \([0,v_{\text{oct}}]\). The existence of geometrically maximal knots implies that \( v_{\text{oct}} \in \text{Spec}_{\text{vol}} \). In Lemma 4.1 we describe \emph{geometrically minimal} sequences of links, i.e. those with volume density approaching 0. Hence \( 0 \in \text{Spec}_{\text{vol}} \). It was shown by Champanerkar, Kofman, and Purcell in [6] that \( 2v_{\text{tet}} \in \text{Spec}_{\text{vol}} \). We are able to prove the following theorem.

\begin{theorem}
The set \( C_{\text{vol}} \) of volume densities of hyperbolic links is a dense subset of \([0,v_{\text{oct}}]\), and \( \text{Spec}_{\text{vol}} = [0,v_{\text{oct}}] \). In other words, given \( x \in [0,v_{\text{oct}}] \) there exists a sequence \( \{K_n\}_{n=1}^{\infty} \) of hyperbolic links such that the volume densities satisfy \( \lim_{n \to \infty} d_{\text{vol}}(K_n) = x \).
\end{theorem}

Another invariant that was studied in [4] and [5] was the \emph{determinant density}, \( d_{\text{det}}(K) \) of a link \( K \), which is defined by the equation

\[ d_{\text{det}}(K) := \frac{2\pi \log(\det(K))}{c(K)} \]

It is shown in [5] that there are sequences \( \{K_n\}_{n=1}^{\infty} \) of links such that \( \lim_{n \to \infty} d_{\text{det}}(K_n) = v_{\text{oct}} \) (see Theorem 2.4 of this paper). Such sequences are called \emph{diagrammatically maximal}. We define \( C_{\text{det}} = \{d_{\text{det}}(K) : K \text{ is a (not necessarily hyperbolic) link} \} \subseteq \mathbb{R} \) and define \( \text{Spec}_{\text{vol}} \) to be the set of limit points of \( C_{\text{det}} \). We call \( \text{Spec}_{\text{det}} \) the \emph{spectrum of determinant densities}.

It is interesting to study the relationships between \( \text{Spec}_{\text{vol}} \) and \( \text{Spec}_{\text{det}} \). While we know that \( \text{Spec}_{\text{vol}} \subseteq [0,v_{\text{oct}}] \), it is unknown whether \( v_{\text{oct}} \) forms an upper bound for \( \text{Spec}_{\text{det}} \). However, it is a conjecture [3] Conjecture 1.1] that \( v_{\text{oct}} \) is an upper bound for \( \text{Spec}_{\text{det}} \). We are able to prove the following theorem.

\begin{theorem}
The spectrum of determinant densities \( \text{Spec}_{\text{det}} \) contains \([0,v_{\text{oct}}]\). In other words, given any \( x \in [0,v_{\text{oct}}] \) there exists a sequence \( \{K_n\}_{n=1}^{\infty} \) of links satisfying \( \lim_{n \to \infty} d_{\text{det}}(K_n) = x \).
\end{theorem}

In [3] and [5] it is shown that \( 0,v_{\text{oct}} \in \text{Spec}_{\text{vol}} \cap \text{Spec}_{\text{det}} \), and the authors ask what this intersection is. As a corollary of Theorems 1.2 and 1.3 we obtain:

\begin{corollary}
\end{corollary}
Corollary 1.4. The intersection $\text{Spec}_{\text{vol}} \cap \text{Spec}_{\text{det}}$ is equal to $[0, v_{\text{oct}}]$.

Since $\text{Spec}_{\text{vol}}$ considers only the densities of hyperbolic links, it is useful to know what determinant densities are realized by hyperbolic links. We show in Theorem 5.3 that the set of determinant densities of hyperbolic links is also dense in $[0, v_{\text{oct}}]$.

Shortly after the author posted the results of this paper, Colin Adams, Aaron Calderon, Xinyi Jiang, Alexander Kastner, Gregory Kehne, Nathaniel Mayer, and Mia Smith [2] independently proved results similar to those in this paper. In particular, they proved that the set of volume densities is dense in $[0, v_{\text{oct}}]$ and that the set of determinant densities is also dense in $[0, v_{\text{oct}}]$. Their proof is similar to the one found in this paper. They consider knots similar to the knots $N(W_{n,n})$ of Definition 3.2 of this paper, and they cite work of Futer, Kalfagianni, and Purcell [9] and Thurston [17] to obtain volume bounds. We likewise cite [17], and we cite a result of Futer, Kalfagianni, and Purcell [10], which was derived from [9], to obtain our volume bounds.

Acknowledgements. The author would like to thank his adviser Efstratia Kalfagianni for help in preparing the paper and for getting him started on this project. The author would also like to thank Jessica Purcell for conversations that were beneficial, especially with the proof Theorem 1.3. Conversations with Ilya Kofman were helpful, especially with Theorem 5.3. The author appreciates input from Abhijit Champanerkar and inspirational remarks made by Colin Adams at the AMS meeting in East Lansing.

2. Background

2.1. Geometrically Maximal and Diagrammatically Maximal Links. In this subsection we recall definitions and results from [5]. Given a link $K \subset \mathbb{R}^3$ we define the projection graph $G(K)$ to be the 4-valent graph obtained by projection of $K$ onto $\mathbb{R}^2 \times \{0\}$.

Definition 2.1. Let $G$ be a possibly infinite graph. For any finite subgraph $H$, let $\partial H$ be the set of vertices of $H$ that share an edge with a vertex not in $H$. Let $|\cdot|$ denote the number of vertices in a finite graph. An exhaustive nested sequence of finite, connected subgraphs $\{H_n \subseteq G : H_n \subseteq H_{n+1}, \bigcup_{n=0}^{\infty} H_n = G\}$ is a Følner sequence for $G$ if

$$\lim_{n \to \infty} \frac{|\partial H_n|}{|H_n|} = 0.$$ 

The graph $G$ is amenable if a Følner sequence for $G$ exists. In particular, the infinite square lattice (i.e. the projection graph of $W$) is amenable.

Given a link $K$ in $S^3$, a Conway sphere is a 2-sphere in $S^3$ intersecting $K$ transversely in four points. Using Conway spheres, we will define a cycle of tangles, which is an important definition for the statement of Theorem 2.3.

Definition 2.2. A Conway sphere is called visible if it is parallel to one dividing the diagram into two tangles, as in Figure 2.1. A tangle is called knotty if it is nontrivial, and not a (portion of a) single twist region; i.e. not a rational tangle of type $n$ or $1/n$ for $n \in \mathbb{Z}$. We will say that $K_n$ contains a cycle of tangles if $K_n$ contains a visible Conway sphere with a knotty tangle on each side.

The following theorem was proved by Champanerkar, Kofman, and Purcell.

Theorem 2.3 ([5 Theorem 1.4]). Let $K_n$ be any sequence of hyperbolic alternating link diagrams that contain no cycle of tangles, such that

1. there are subgraphs $G_n \subseteq G(K_n)$ that form a Følner sequence for $G(W)$, and
2. $\lim_{n \to \infty} \frac{|G_n|}{c(K_n)} = 1.$
Figure 2.1. The dashed line represents a visible Conway sphere.

Then \( \{K_n\}_{n=0}^\infty \) is geometrically maximal: 
\[ \lim_{n \to \infty} \frac{\text{vol}(K_n)}{c(K_n)} = v_{\text{oct}}. \]

The following theorem, proved in [5, Theorem 1.5], gives a similar statement for diagrammatically maximal links.

**Theorem 2.4.** Let \( \{K_n\}_{n=0}^\infty \) be a sequence of alternating link diagrams such that

1. there are subgraphs \( G_n \subseteq G(K_n) \) that form a Følner sequence for \( G(W) \), and
2. \( \lim_{n \to \infty} \frac{|G_n|}{c(K_n)} = 1. \)

Then \( \{K_n\}_{n=0}^\infty \) is diagrammatically maximal: 
\[ \lim_{n \to \infty} \frac{\text{det}(K_n)}{c(K_n)} = v_{\text{oct}}. \]

Note that the cycle of tangles condition is not necessary in the construction of diagrammatically maximal links. This is one reason motivating Theorem 3.1, which states that there are geometrically maximal sequences of links containing a cycle of tangles.

2.2. Conway Sums and Belted Sums of Links. Let \( T \) be a 2-tangle. There are two ways to close the tangle \( T \) to form a link. Denote these closures \( N(T) \) and \( D(T) \) as depicted in Figure 2.2. The closure \( N(T) \) is called the numerator closure and \( D(T) \) is called the denominator closure. Next, one may add an extra component, \( C \), called the belt component, to the link \( N(T) \) in the following manner. Let \( C \) be an unknotted circle that lies in a plane orthogonal to the projection plane and encircles the arcs added to \( T \) to form \( N(T) \), as in Figure 2.2. The resulting link, \( B(T) \), is the belted link corresponding to \( T \) or simply the belted tangle.

Given two tangles \( T_1 \) and \( T_2 \) such that \( B(T_1) \) and \( B(T_2) \) are hyperbolic, one may form the belted sum of \( B(T_1) \) and \( B(T_2) \) as follows. Let \( M_i \) be the link complement \( S^3 \backslash B(T_i) \), for \( i = 1, 2 \). Work of Adams [3] shows that the belt component \( C_i \) of \( T_i \) bounds a totally geodesic, twice-punctured disk in \( M_i \). Cut each \( M_i \) along this twice-punctured disk to form a manifold \( M'_i \). By Adams [3], there is a unique hyperbolic structure on a twice-punctured disk. Therefore we may glue \( M'_1 \) to \( M'_2 \) via an isometry of twice-punctured disks that maps \( C_1 \) to \( C_2 \). The result is a link, denoted \( B(T_1) + B(T_2) \), which we call the belted sum of \( B(T_1) \) and \( B(T_2) \). See Figure 2.3.
The following theorem about belted sums of links will be important in the proofs of Theorems 1.2, 3.1, 3.3.

**Lemma 2.5** ([3, Corollary 5.2]). Suppose that \( n \) belted tangles \( B(T_1), \ldots, B(T_n) \) are hyperbolic with finite volume. Then the belted sum \( B(T_1) + \ldots + B(T_n) \) is also a hyperbolic link and has volume \( \text{vol}(B(T_1)) + \ldots + \text{vol}(B(T_n)) \).

In addition to the belted sum of belted tangles, we can sum tangles in the manner described below.

**Definition 2.6.** Let \( T_1 \) and \( T_2 \) be 2-tangle diagrams. One may connect these 2-tangle diagrams as indicated in Figure 2.4 to form the 2-tangle \( T_1 + T_2 \). We call \( T_1 + T_2 \) the tangle sum, or Conway sum of \( T_1 \) and \( T_2 \).

Lemma 2.5 showed that volume is additive under belted sums of tangles. Similarly, we have the following lemma describing the determinant of a Conway sum of tangles.

**Lemma 2.7.** Let \( T_1, \ldots, T_n \) be tangles and let \( T = T_1 + \ldots + T_n \) be the tangle sum. Then

\[
\det(D(T)) = \prod_{i=1}^{n} \det(D(T_i)).
\]

**Proof.** When \( n = 2 \) we have the following well-known fact:

\[
\det(D(T_1 + T_2)) = \det(D(T_1) \# D(T_2)) = \det(D(T_1)) \det(D(T_2))
\]
The result now follows by induction. □

We now recall a result of Futer, Kalfagianni, and Purcell [10] which will play an important role in the proofs of Theorems 3.1, 3.3, and 1.2. We begin with the following definition. A tangle $T$ is an east-west twist if $N(T)$ is the standard diagram of a $(2,q)$-torus link. To simplify notation throughout, we define $\xi_n$ as follows:

$$(2.1) \quad \xi_n := \left( 1 - \left( \frac{8\pi}{11.524 + n\sqrt{2}} \right)^2 \right)^{3/2}$$

Note that $\lim_{n \to \infty} \xi_n = 1$.

**Theorem 2.8.** Let $T_1, \ldots, T_n, n \geq 12$, be tangles admitting prime, alternating diagrams, none of which is an east-west twist. Let $K$ be the numerator closure of the Conway sum $N(T_1 + \ldots + T_n)$. Let $L$ be the belted sum $B(T_1) + \ldots + B(T_n)$. Then $K$ is hyperbolic and

$$\text{(2.2) } \text{vol}(K) \geq \xi_n \text{vol}(L)$$

**Proof.** This follows directly from the proof of [10, Theorem 1.5] as follows. In the second to last line of that proof, the authors showed that

$$\text{(2.3) } \text{vol}(K) \geq \left( 1 - \left( \frac{2\pi}{\ell_{\text{min}}} \right)^2 \right)^{3/2} \text{vol}(L)$$

where $\ell_{\text{min}}$ is the minimum possible length of the meridian of the belt. They also showed in the same proof that $\ell_{\text{min}} \geq 11.524 + n\sqrt{2}$, hence $\text{vol}(K) \geq \xi_n \text{vol}(L)$. □

We record here the following well-known theorem of W. Thurston follows from [17, Theorem 3.4].

**Theorem 2.9.** Suppose that $M_1$ is a complete, finite-volume, hyperbolic manifold and that $M_2 \neq M_1$ is a complete hyperbolic manifold obtained from $M_1$ by Dehn filling along one of the cusps. Then $\text{vol}(M_1) > \text{vol}(M_2)$.

2.3. Adequate Tangles. We state some results about adequate link diagrams that will play an important role in the proofs of Theorems 3.1, 3.3, 1.2, and 1.3. For the definition of an adequate link diagram and nugatory crossings, see [14, Definition 5.2].

**Definition 2.10.** A link diagram $D \subset S^2$ is prime if any simple closed curve in $S^2$ that meets $D$ transversely at two points bounds, on one side of it, a disk that intersects $D$ in a diagram $U$ of the unknotted ball-arc pair. The diagram $D$ is strongly prime if, in addition, $U$ is the zero-crossing diagram.

We will use the following theorem, which follows from [8, Corollary 3.21] to show that a link diagram is prime.

**Theorem 2.11.** Suppose that $K$ is a non-split, prime link. Then every adequate diagram of $K$ without nugatory crossings is prime.

The following proposition gives a way to show that a link is non-alternating. We will use this in the proof of Theorem 3.3 where we show that there exist geometrically maximal sequences of non-alternating links.

**Proposition 2.12.** If $L$ has a prime, non-alternating, adequate diagram, then $L$ is non-alternating.
Proof. Let $L$ be a link and $D$ a diagram for $L$ having $n$ crossings. Let breadth($L$) be the breadth of the Jones polynomial for $L$, in other words, the difference between the maximal and minimal degrees of the Jones polynomial for $L$. We recall the following facts which may be found in [14, Proposition 5.3, Theorem 5.9, and Corollary 5.14].

1. If $D$ is reduced and alternating, then $D$ is adequate.
2. If $D$ is an adequate diagram, then $c(L) = n$.
3. If $D$ is reduced and alternating, then breadth($L$) = $n$.
4. If $D$ is non-alternating and prime, then breadth($L$) < $n$.

Suppose $D_1$ is a prime, non-alternating, adequate diagram for $L$, and that $D_2$ is an alternating diagram for $L$. By removing nugatory crossings, we may assume that $D_2$ is a reduced, alternating diagram. Therefore both $D_1$ and $D_2$ are adequate diagrams and have the same number of crossings by facts (1) and (2) above. Let $n$ be the number of crossings in $D_1$ (or $D_2$). Since $D_1$ is non-alternating, fact (4) above implies breadth($L$) < $n$. On the other hand, since $D_2$ is reduced and alternating, fact (3) implies that breadth($L$) = $n$, a contradiction. □

Definition 2.13. A tangle diagram $T$ is adequate if the diagrams of both $N(T)$ and $D(T)$ are adequate. In the event that both closures produce reduced, alternating diagrams, the tangle $T$ is said to be strongly alternating. A strongly alternating tangle is adequate.

Proposition 2.14. The tangle sum of $n$ adequate tangles is adequate for $n \geq 2$.

Proof. It follows from work of Lickorish and Thistlethwaite [15, Proposition 4] that the tangle sum of two adequate tangles is adequate. The proposition readily follows by induction on $n$. □

We close this section with the following corollary showing that crossing number of adequate tangles is additive. This plays a key role in the proof of Theorems 1.2 and 1.3.

Corollary 2.15. Let $T_1, \ldots, T_n$ be adequate tangle diagrams and let $c(N(T_i))$ be the crossing number of the closure for $i = 1, \ldots, n$. Let $T_1 + \ldots + T_n$ be the tangle sum. Then the crossing numbers satisfy

\[ c(N(T_1 + \ldots + T_n)) = c(N(T_1)) + \ldots + c(N(T_n)) \]
\[ c(D(T_1 + \ldots + T_n)) = c(D(T_1)) + \ldots + c(D(T_n)) \]

Proof. The natural diagram representing the link $N(T_1 + \ldots + T_n)$ as a Conway sum has $c(N(T_1)) + \ldots + c(N(T_n))$ crossings. Since $T_1, \ldots, T_n$ are adequate, we know that $N(T_1 + \ldots + T_n)$ is adequate by Proposition 2.14. Note that an adequate diagram of a link has the minimal number of crossings by Proposition 2.12. Therefore $c(N(T_1 + \ldots + T_n)) = c(N(T_1)) + \ldots + c(N(T_n))$. The proof that $c(D(T_1 + \ldots + T_n)) = c(D(T_1)) + \ldots + c(D(T_n))$ is similar. □

3. Non-alternating Geometrically Maximal Knots

We now address the question of whether all the conditions in Theorem 2.3 are necessary. We begin with a construction of a geometrically maximal sequence of links for which each link contains a cycle of tangles.

Theorem 3.1. Let $\{T_i\}_{i=1}^\infty$ be a sequence of tangles admitting prime, alternating diagrams, none of which is an east-west twist. Let $K_i = N(T_i)$ for all $i$. Suppose that each $K_i$ is hyperbolic and that the sequence $\{K_i\}_{i=1}^\infty$ is geometrically maximal. For each $n \in \mathbb{N}$, let $T(n)$ be the Conway sum of $n$ copies of $T_n$, and define $K(n) = N(T(n))$. Then $K(n)$ is hyperbolic whenever $n \geq 12$, and the sequence $\{K(n)\}_{n=1}^\infty$ is a geometrically maximal sequence of links, all but one of which contains a cycle of tangles.
Proof. By construction, whenever \( n \geq 2 \), we have that \( K(n) \) contains a cycle of tangles. Moreover, whenever \( n \geq 12 \) we have from Theorem 2.8 that \( K(n) \) is hyperbolic. We now show that the sequence \( \{ K(n) \}_{n=1}^\infty \) is geometrically maximal. Let \( L_1 = B(T_1) \), the belted link corresponding to \( L_1 \), and for each \( n \in \mathbb{N} \) let \( L(n) \) be the belted sum of \( n \) copies of \( L_n \). By Theorem 2.8 we have that \( \text{vol}(K(n)) \geq \xi_n \text{vol}(L(n)) \) where \( \xi_n \) was defined in (2.1). We obtain 

\[
\text{vol}(L(n)) = \sum_{i=1}^{n} \text{vol}(L_n) = n \text{vol}(L_n) > n \text{vol}(K_n)
\]

by Theorem 2.9 (3.1)

Observe that \( c(K(n)) \leq n c(K_n) \) since the natural diagram demonstrating \( K(n) \) as a Conway sum has \( n c(K_n) \) crossings. Therefore 

\[
\frac{\text{vol}(K(n))}{c(K(n))} \geq \frac{\text{vol}(K(n))}{n c(K_n)} \geq \xi_n \frac{\text{vol}(L(n))}{n c(K_n)} = \frac{\xi_n}{n c(K_n)} \text{vol}(K_n)
\]

by Theorem 2.9

(3.2)

Note that \( \lim_{n \to \infty} \xi_n = 1 \). Since \( \{ K_n \}_{n=1}^\infty \) is geometrically maximal, we know that 

\[
\lim_{n \to \infty} \frac{\text{vol}(K_n)}{c(K_n)} = v_{\text{oct}}
\]

hence by (3.2) we obtain 

\[
\lim_{n \to \infty} d_{\text{vol}}(K(n)) = \lim_{n \to \infty} \frac{\text{vol}(K(n))}{c(K(n))} \geq \lim_{n \to \infty} \xi_n \frac{\text{vol}(K_n)}{c(K_n)} = v_{\text{oct}}
\]

Moreover, \( d_{\text{vol}}(K(n)) \leq v_{\text{oct}} \) for all \( n \), as this is true for any link. Therefore \( \{ K(n) \}_{n=1}^\infty \) is geometrically maximal. \( \square \)

We can use a method similar to the proof of Theorem 3.1 to prove that there exist geometrically maximal sequences of non-alternating links. We will construct a specific example of such a sequence. We begin by considering a family of weaving tangles in Definition 3.2. By taking a Conway sum of these weaving tangles and their reflections (i.e. the result of changing each over-crossing to an under-crossing and vice versa), we will obtain a geometrically maximal sequence of non-alternating links.

**Definition 3.2.** Let \( B_m \) be the braid group on \( m \) strings. For \( i = 1, \ldots, m-1 \), let \( \sigma_i \in B_m \) be the \( i \)th Artin generator, i.e. the group element corresponding to twisting the \( i \)th strand under the \((i+1)\)st strand. Let \( L_{m,n} \) be the element \((\sigma_1 \sigma_2^{-1} \sigma_3 \sigma_4^{-1} \ldots \sigma_{m-1}^{-1})^n \in B_m \) depicted on the left hand side of Figure 3.1. Let \( W_{m,n} \) be the result of closing all but the second and third strands of the braid as in the right hand side of Figure 3.1. We will call \( W_{m,n} \) the weaving tangle of order \( n \) on \( m \) strands. The knots \( N(W_{m,n}) \) are the weaving knots of [6].

**Theorem 3.3.** There exist geometrically maximal sequences of non-alternating links.

**Proof.** Let \( W_{k,k} \) be the weaving tangle and let \( \overline{W}_{k,k} \) be its reflection, i.e. the result of changing each over-crossing to an under-crossing and vice versa. For \( n \geq 1 \) define 

\[
K(n) = N(W_{n,n} + \overline{W}_{n,n} + \ldots + W_{n,n} + \overline{W}_{n,n})
\]
to be the closure of the Conway sum of \( n \) copies of \( W_{n,n} \) with \( n \) copies of \( \overline{W}_{n,n} \) as indicated in Figure 3.2. Let \( K_n = N(W_{n,n}) \) and \( \overline{K}_n = N(\overline{W}_{n,n}) \), and \( L_n = B(W_{n,n}) \) and \( \overline{L}_n = B(\overline{W}_{n,n}) \). Note that \( K_n \) and \( \overline{K}_n \) are Dehn fillings of \( L_n \) and \( \overline{L}_n \), respectively.

We prove that the sequence \( \{K(n)\}_{n=1}^\infty \) is geometrically maximal. First, observe that when \( n \geq 6 \), Theorem 2.8 implies that \( K(n) \) is hyperbolic. Let

\[
L(n) = B(W_{n,n}) + B(\overline{W}_{n,n}) + \ldots + B(W_{n,n}) + B(\overline{W}_{n,n})
\]

be the belted sum of \( n \) copies of \( B(W_{n,n}) \) with \( n \) copies of \( B(\overline{W}_{n,n}) \). Similar to the proof of Theorem 3.1 we have

\[
\text{vol}(L(n)) = \sum_{i=1}^{n} (\text{vol}(L_n) + \text{vol}(\overline{L}_n)) \quad \text{by Lemma 2.5}
\]

\[
= n[\text{vol}(L_n) + \text{vol}(\overline{L}_n)]
\]

(3.3) \[
> n[\text{vol}(K_n) + \text{vol}(\overline{K}_n)] \quad \text{by Theorem 2.9}
\]
Since $K_n$ and $\overline{K_n}$ are reduced and alternating, by counting the number of crossings in Figure 3.1 and using Proposition 2.12, we find that $c(K_n) = c(\overline{K_n}) = n(n-1)$. Now the diagram of $K(n)$ depicted in Figure 3.2 has $2n^2(n-1)$ crossings, implying $c(K(n)) \leq 2n^2(n-1)$. Therefore

$$\frac{\text{vol}(K(n))}{c(K(n))} \geq \frac{\text{vol}(K(n))}{2n^2(n-1)} \geq \frac{\xi_2n \text{vol}(L(n))}{2n^2(n-1)}$$

by Theorem 2.8

$$> \frac{\xi_2n [\text{vol}(K_n) + \text{vol}(\overline{K_n})]}{2n^2(n-1)}$$

by (3.3)

$$= \frac{\xi_2n}{2} \left( \frac{\text{vol}(K_n)}{c(K_n)} + \frac{\text{vol}(\overline{K_n})}{c(\overline{K_n})} \right)$$

(3.4)

$$= \frac{\xi_2n}{2} [d(K_n) + d(\overline{K_n})]$$

(3.5)

Both $K_n$ and $\overline{K_n}$ are geometrically maximal by Theorem 2.3, so $\lim_{n \to \infty} d(K_n) = \lim_{n \to \infty} d(\overline{K_n}) = v_{\text{oct}}$. Moreover, $\lim_{n \to \infty} \xi_2n = 1$, so (3.5) implies that

$$\lim_{n \to \infty} d(K(n)) = v_{\text{oct}}.$$

We show that $K(n)$ is non-alternating. Let $D$ be the diagram shown in Figure 3.2. Observe that $D$ is non-alternating. Since $W_{k,k}$ and $\overline{W_{k,k}}$ are strongly alternating (hence adequate) tangle diagrams, Proposition 2.14 implies that $D$ is adequate. Next, we establish the conditions needed to apply Theorem 2.11. An adequate (hence minimal crossing) diagram of a split link must also be split. Since $D$ is non-split, it follows that $K(n)$ is non-split. Now $K(n)$ is hyperbolic when $n \geq 6$, as noted above. Therefore $K(n)$ is a prime link. It now follows from Theorem 2.11 that the diagram $D$ is prime. Proposition 2.12 now implies that $K(n)$ is non-alternating.$\square$

Remark: The sequence of links $\{K(n)\}_{n=1}^{\infty}$ in the proof of Theorem 3.3 is geometrically maximal and each link of the sequence contains a cycle of tangles.

4. The Spectrum of Volume Densities

We now turn to the proof that the set of volume densities is dense in $[0, v_{\text{oct}}]$. In Lemma 4.1, we prove the existence of tangles whose closures form a geometrically minimal sequence of links, i.e. a sequence links with volume density approaching 0. On the other hand, Lemma 4.2 produces a sequence of tangles whose closures form a geometrically maximal sequence of links.

The idea of the proof of Theorem 1.2 is to combine geometrically maximal tangles with geometrically minimal tangles via Conway sum. Key to the proof is the fact that hyperbolic volume is additive under belted sum (see Lemma 2.5), and that the crossing number of adequate tangles is additive under Conway sum (see Corollary 2.15). The ratio of geometrically maximal to geometrically minimal tangles may then be controlled so that one may find a sequence of links with volume density approaching any number in the interval $[0, v_{\text{oct}}]$.

Lemma 4.1. There exists a sequence of strongly alternating tangles $\{T_m\}_{m=1}^{\infty}$ such that

$$\lim_{m \to \infty} d_{\text{vol}}(N(T_m)) = 0$$

and $N(T_m)$ is hyperbolic for all $m \geq 7$. 
Let \( P_{\ell, m, n} \) be the pretzel tangle shown in Figure 4.1. It is well-known that many pretzel links are hyperbolic. For example, whenever \( \ell, m, n \geq 7 \), work of Futer, Kalfagianni, and Purcell [9, Theorem 1.2] implies that \( N(P_{\ell, m, n}) \) is hyperbolic. Moreover, \( P_{\ell, m, n} \) is strongly alternating whenever \( \ell, m \), and \( n \geq 2 \). Fix \( \ell \geq 7 \) and \( n \geq 7 \) and let \( K_m = N(P_{\ell, m, n}) \). By work of Lackenby, Agol, and D. Thurston [13], we know that \( \text{vol}(K_m) \leq 10 \text{v}_{\text{tet}}(\text{tw}(K_m) - 1) \), where \( \text{tw}(K_m) \) is the number of twist regions in a diagram of \( K_m \). In particular, \( \text{tw}(K_m) = 3 \) for all values of \( m \) so \( \text{vol}(K_m) \leq 20 \text{v}_{\text{tet}} \). It follows that

\[
\lim_{m \to \infty} d_{\text{vol}}(K_m) = \lim_{m \to \infty} \frac{\text{vol}(K_m)}{c(K_m)} \leq \lim_{m \to \infty} \frac{20 \text{v}_{\text{tet}}}{\ell + m + n} = 0
\]

\[\square\]

**Lemma 4.2.** There exists a sequence of strongly alternating (hence adequate) tangles \( \{T_n\}_{n=1}^{\infty} \) such that \( \{N(T_n)\}_{n=1}^{\infty} \) is geometrically maximal.

**Proof.** Consider the weaving tangles \( W_{m, n} \) from Definition 3.2 and depicted in Figure 3.1. Let \( T_n = W_{n, n} \). It was shown in [6] that \( \{N(T_n)\}_{n=1}^{\infty} \) is a geometrically maximal sequence of links. Note that \( N(T_n) \) and \( D(T_n) \) have reduced, alternating diagrams, whenever \( n \geq 4 \).

We have established examples of geometrically minimal and geometrically maximal sequences of adequate links. We restate and prove Theorem 1.2.

**Theorem 1.2.** The set \( C_{\text{vol}} \) of volume densities of hyperbolic links is a dense subset of \([0, v_{\text{oct}}]\), and \( \text{Spec}_{\text{vol}} = [0, v_{\text{oct}}] \). In other words, given \( x \in [0, v_{\text{oct}}] \) there exists a sequence \( \{K_n\}_{n=1}^{\infty} \) of hyperbolic links such that the volume densities satisfy

\[
\lim_{n \to \infty} d_{\text{vol}}(K_n) = x.
\]

**Proof.** It suffices to show that for any non-negative integers \( a \) and \( b \) with \( a \) and \( b \) not both zero, and any \( \epsilon > 0 \), there exists a link \( K \) such that

\[
\frac{b}{a + b} v_{\text{oct}} - \epsilon < d_{\text{vol}}(K) < \frac{b}{a + b} v_{\text{oct}} + \epsilon.
\]
Let $\epsilon > 0$ be arbitrary. Let $P_{\ell,m,n}$ be the pretzel tangles from Lemma 4.1. Let $\widetilde{T}_1 = P_{7,\tilde{m},7}$ and $\tilde{K}_1 = N(\widetilde{T}_1)$, where $\tilde{m}$ is chosen to be large enough that

$$ 40a \frac{v_{tet}}{(a + b)(\tilde{m} + 14)} < \frac{\epsilon}{2} \quad (4.1) $$

In Lemma 4.2 it was pointed out that the sequence of links $\{N(W_{k,k})\}_{k=1}^\infty$, where $W_{k,k}$ is the weaving tangle, is a geometrically maximal sequence of links. Therefore we may choose $T_2 = W_{k,k}$ and $K_2 = N(T_2)$ with $k$ sufficiently large that

$$ \frac{\text{vol}(K_2)}{c(K_2)} > \frac{(a + b)}{b} \left(1 + \frac{40a}{(a + b)(m + 14)}\right) \quad (4.2) $$

Since $\tilde{K}_1$ and $K_2$ have reduced alternating diagrams, by counting the number of crossings in these diagrams, we see that

$$ k(k - 1) = c(K_2) \geq c(\tilde{K}_1) = m + 14. \quad (4.3) $$

Let $m = k(k - 1) - 14$. Define $T_1 = P_{7,m,7}$ and $K_1 = N(T_1)$. This choice of $m$ implies that

$$ c(K_1) = c(K_2) \quad (4.4) $$

Observe that $m \geq \tilde{m}$, $tw(K_1) = 3$ and $c(K_1) = m + 14$, so (4.1) guarantees that

$$ \frac{10a v_{tet}(tw(K_1) + 1)}{(a + b)c(K_1)} = \frac{40a v_{tet}}{(a + b)(m + 14)} \leq \frac{40a v_{tet}}{(a + b)(\tilde{m} + 14)} < \frac{\epsilon}{2} \quad (4.5) $$

Choose $n \geq 12$ so that $\xi_n$ as defined in (2.1) satisfies

$$ \xi_n > \max \left\{ 1 - \frac{(a + b)e}{2b v_{oct} - \epsilon(a + b)} : \frac{2bv_{oct}}{2b v_{oct} + \epsilon(a + b)} \right\} \quad (4.6) $$

Since $0 < \xi_n < 1$, we need to check that such a choice of $n$ is possible. Since $a$, $b$, $v_{oct}$, and $\epsilon$ are positive we know that

$$ 0 < \frac{2bv_{oct}}{2b v_{oct} + \epsilon(a + b)} < 1 $$

Moreover, as long as $\epsilon < 2v_{oct}/(a + b)$ we have $2b v_{oct} > \epsilon(a + b)$, hence

$$ 1 - \frac{(a + b)e}{2b v_{oct} - \epsilon(a + b)} < 1 $$

Let $L_1 = B(T_1)$ and $L_2 = B(T_2)$ be the belted links corresponding to $T_1$ and $T_2$ respectively. Form the link $L$ by taking the belted sum of $a \cdot n$ copies of $L_1$ with $b \cdot n$ copies of $L_2$. Let $K$ be the result of filling the belt of $L$ via the meridional Dehn filling. Note that $K$ is simply the result of taking the closure of the tangle sum of $a \cdot n$ copies of $T_1$ with $b \cdot n$ copies of $T_2$ as shown in Figure 4.2. We obtain

$$ \text{vol}(K) \geq \xi_n \text{vol}(L) \quad \text{by Theorem 2.8} \quad (4.7) $$

$$ = \xi_n(a \cdot n \cdot \text{vol}(L_1) + b \cdot n \cdot \text{vol}(L_2)) \quad \text{by Lemma 2.6} \quad (4.8) $$

$$ > \xi_n(a \cdot n \cdot \text{vol}(K_1) + b \cdot n \cdot \text{vol}(K_2)) \quad \text{by Theorem 2.9} \quad (4.9) $$

Since $T_1$ and $T_2$ are strongly alternating tangles, it follows from Corollary 2.15 that

$$ c(K) = n \cdot a \cdot c(K_1) + n \cdot b \cdot c(K_2) \quad (4.10) $$
This produces the following inequalities to form a lower bound for the density $d_{vol}(K)$.

\[
d(K)_{vol} = \frac{\text{vol}(K)}{c(K)} > \frac{\xi_n(a \cdot n \cdot \text{vol}(K_1) + b \cdot n \cdot \text{vol}(K_2))}{c(K)}
\]

\[
= \frac{\xi_n(a \cdot n \cdot \text{vol}(K_1) + b \cdot n \cdot \text{vol}(K_2))}{a \cdot n \cdot c(K_1) + b \cdot n \cdot c(K_2)}
\]

\[
= \xi_n \frac{\text{vol}(K_1)}{c(K_1)} \frac{a}{a+b} + \xi_n \frac{\text{vol}(K_2)}{c(K_2)} \frac{b}{a+b}
\]

\[
\geq \xi_n \frac{\text{vol}(K_2)}{c(K_2)} \frac{b}{a+b}
\]

\[
> \left(1 - \frac{\epsilon(a+b)}{2b v_{oct} - \epsilon(a+b)}\right) \left(v_{oct} - \frac{a+b}{b} \epsilon \right) \frac{b}{a+b}
\]

\[
= \left(1 - \frac{\epsilon(a+b)}{2b v_{oct} - \epsilon(a+b)}\right) \left(v_{oct} \frac{b}{a+b} - \frac{\epsilon}{2}\right)
\]

\[
= v_{oct} \frac{b}{a+b} - \frac{2b v_{oct} - \epsilon(a+b)}{2} + \frac{\epsilon^2(a+b)}{2} - \frac{\epsilon}{2}
\]

\[
= v_{oct} \frac{b}{a+b} + \frac{\epsilon}{2} \left(\frac{-2 v_{oct} b}{2b v_{oct} - \epsilon(a+b)} + \frac{\epsilon(a+b)}{2b v_{oct} - \epsilon(a+b)}\right) - \frac{\epsilon}{2}
\]

\[
= v_{oct} \frac{b}{a+b} - \epsilon
\]

We now find an upper bound for $d_{vol}(K)$. Since $K$ is obtained from $L$ by Dehn filling, Theorem 2.9 implies that $\text{vol}(K) < \text{vol}(L)$. Moreover, Lemma 2.5 implies that $\text{vol}(L) = a \cdot n \cdot \text{vol}(L_1) + b \cdot n \cdot \text{vol}(L_2)$. Therefore

\[
(4.11) \quad \text{vol}(K) < a \cdot n \cdot \text{vol}(L_1) + b \cdot n \cdot \text{vol}(L_2)
\]

It was shown by Lackenby, Agol, and D. Thurston [13] that $a \cdot n \cdot \text{vol}(L_1) < 10 a \cdot n \cdot v_{tet}(\text{tw}(L_1) - 1)$. Consider the diagrams of $L_1$ and $K_1$. Adding the belt circle to $K_1$ to form $L_1$ adds no more than two twist regions, as indicated in Figure 4.3. Therefore $\text{tw}(L_1) \leq \text{tw}(K_1) + 2$, hence

\[
(4.12) \quad a \cdot n \cdot \text{vol}(L_1) < 10 a n v_{tet}(\text{tw}(K_1) + 1)
\]
Define $L^n_2$ to be the belted sum of $n$ copies of $L_2$ and let $K^n_2$ be the result of filling the belt of $L^n_2$ via the meridional filling. Then $K^n_2 = N(T_2 + \ldots + T_3)$ where $+$ denotes Conway sum and the sum consists of $n$ copies of $T_2$ (see Figure 4.4). Then Lemma 2.5 implies $\text{vol}(L^n_2) = n \cdot \text{vol}(L_2)$. Theorem 2.8 implies $\text{vol}(L^n_2) \leq \text{vol}(K^n_2)/\xi_n$. Therefore

\begin{equation}
 b \cdot n \cdot \text{vol}(L_2) = b \cdot \text{vol}(L^n_2) \leq \frac{b}{\xi_n} \text{vol}(K^n_2) \tag{4.13}
\end{equation}

Since $v_{\text{oct}}$ forms an upper bound on volume density, we know that $\text{vol}(K^n_2) \leq v_{\text{oct}}(K^n_2)$. It follows that

\begin{equation}
 \frac{b}{\xi_n} \text{vol}(K^n_2) \leq \frac{b}{\xi_n} v_{\text{oct}}(K^n_2) \tag{4.14}
\end{equation}

The diagram for $K^n_2$ shown in Figure 4.4 has $n \cdot c(K_2)$ crossings. Therefore $c(K^n_2) \leq n \cdot c(K_2)$. This yields

\begin{equation}
 \frac{b}{\xi_n} v_{\text{oct}}(K^n_2) \leq \frac{b}{\xi_n} n v_{\text{oct}}(K^n_2) \tag{4.15}
\end{equation}

Summarizing (4.13), (4.14), and (4.15) we see that

\begin{equation}
 b \cdot n \cdot \text{vol}(L_2) \leq \frac{b}{\xi_n} n v_{\text{oct}}(K^n_2) \tag{4.16}
\end{equation}
This allows us to produce an upper bound on the volume density \( d(K) \) as follows.

\[
d_{\text{vol}}(K) = \frac{\text{vol}(K)}{c(K)} < \frac{a \cdot n \cdot \text{vol}(L_1) + b \cdot n \cdot \text{vol}(L_2)}{c(K)} 
\]

by \((4.11)\)

\[
= \frac{a \cdot n \cdot \text{vol}(L_1) + b \cdot n \cdot \text{vol}(L_2)}{a \cdot n \cdot c(K_1) + b \cdot n \cdot c(K_2)} 
\]

by \((4.10)\)

\[
< \frac{10 a n v_{\text{oct}}(\text{tw}(K_1) + 1) + b \xi_n (n v_{\text{oct}} c(K_2))}{a \cdot n \cdot c(K_1) + b \cdot n \cdot c(K_2)} 
\]

by \((4.12)\) and \((4.10)\)

\[
= \frac{10 a v_{\text{oct}}(\text{tw}(K_1) + 1) + b v_{\text{oct}} c(K_2)}{(a + b) c(K_1)} + \frac{b v_{\text{oct}} c(K_2)}{\xi_n (a + b) c(K_2)} 
\]

since \( c(K_1) = c(K_2) \)

\[
< \frac{\epsilon}{2} + \frac{1}{\xi_n a + b} \frac{b v_{\text{oct}}}{a + b} 
\]

by \((4.5)\)

\[
< \frac{\epsilon}{2} + \frac{2 b v_{\text{oct}} + (a + b) b v_{\text{oct}}}{2 b v_{\text{oct}}} \frac{a + b}{a + b} 
\]

by \((4.6)\)

\[
= \frac{\epsilon}{2} + \frac{2 b v_{\text{oct}} + (a + b)}{2(a + b)} 
\]

\[
= \frac{b}{a + b} v_{\text{oct}} + \epsilon 
\]

Therefore

\[
\frac{b}{a + b} v_{\text{oct}} - \epsilon < d_{\text{vol}}(K) < \frac{b}{a + b} v_{\text{oct}} + \epsilon 
\]

as desired.

\( \Box \)

5. The Spectrum of Determinant Densities

We now turn to studying the spectrum of determinant densities. The proof that \( \text{Spec}_{\text{det}} \) contains \([0, v_{\text{oct}}]\) will follow a similar method as the proof of Theorem 1.2. Namely, we note that there exist sequences of diagrammatically maximal links with determinant density approaching \( v_{\text{oct}} \), and there exist sequences of \textit{diagrammatically minimal} links, i.e. those with determinant density near 0. We combine these diagrams via Conway sum, but instead of taking the numerator closure as in the proof of Theorem 1.2 we consider the denominator closure. We will then use the facts that \( \log \det \) is additive under the denominator closure of Conway sums (see Lemma 2.7), and that the crossing number is additive under Conway sums of adequate diagrams (see Corollary 2.15). Then by controlling the ratio of diagrammatically minimal links to diagrammatically maximal links, we may obtain a link that has determinant density near any number \( x \in [0, v_{\text{oct}}] \).

Lemma 5.1. There exists a sequence of adequate tangles \( \{T_m\}_{m=1}^{\infty} \) such that the sequence of closures \( \{D(T_m)\}_{m=1}^{\infty} \) satisfies \( \lim_{m \to \infty} d_{\text{det}}(D(T_m)) = 0 \).

Proof. Let \( P_{\ell,m,n} \) be the pretzel tangles shown in Figure 4.1. Let \( T_m = P_{3,m,3} \) and \( K_m = D(T_m) \). Then the tangles are strongly alternating, hence adequate. It follows from [14] Page 100 (see also work of Dasbach, Kalfagianni, Futer, Lin, and Stoltzfus [7]) that \( \det(K_m) = 6m + 9 \). Now

\[
d_{\text{det}}(K_m) = \lim_{m \to \infty} \frac{2\pi \log \det(K_m)}{c(K_m)} = \lim_{m \to \infty} \frac{2\pi \log(6m + 9)}{m + 6} = 0
\]

\( \Box \)

\(^1\)The author thanks Jessica Purcell for pointing out this reference.
Lemma 5.2. There exists a sequence of adequate tangles \( \{T_m\}_{m=1}^{\infty} \) such that the sequence of closures \( \{D(T_m)\}_{m=1}^{\infty} \) satisfies \( \lim_{n \to \infty} d_{\det}(D(T_n)) = v_{\text{oct}}. \)

Proof. Let \( W_{m,m} \) be the weaving tangles from Definition 3.2 and depicted in Figure 3.1. Then the sequence \( \{D(W_{m,m})\}_{m=1}^{\infty} \) satisfies the conditions of Theorem 2.4, hence is diagrammatically maximal. \( \square \)

Having now established examples of diagrammatically minimal and diagrammatically maximal sequences of links, we can now restate and prove Theorem 1.3.

Theorem 1.3. The spectrum of determinant densities \( \text{Spec}_{\det} \) contains \([0, v_{\text{oct}}]\). In other words, given any \( x \in [0, v_{\text{oct}}] \) there exists a sequence \( \{K_n\}_{n=1}^{\infty} \) of links satisfying \( \lim_{n \to \infty} d_{\det}(K_n) = x. \)

Proof. It suffices to show that for any non-negative integers \( a \) and \( b \) with \( a \) and \( b \) not both zero, and any \( \epsilon > 0 \), there exists a link \( K \) such that

\[
\frac{b}{a + b}v_{\text{oct}} - \epsilon < d_{\det}(K) < \frac{b}{a + b}v_{\text{oct}} + \epsilon.
\]

Let \( \epsilon > 0 \) be arbitrary. Let \( P_{\ell,m,n} \) be the pretzel tangles. Let \( \tilde{T}_1 = P_{3, \tilde{m}, 3} \) and \( \tilde{K}_1 = D(\tilde{T}_1) \), where \( \tilde{m} \) is chosen large enough that

\[
\frac{2\pi \log(6\tilde{m} + 9)}{\tilde{m} + 6} < \left( \frac{a + b}{a} \right) \frac{\epsilon}{2} \tag{5.1}
\]

Since the sequence \( \{D(W_{k,k})\}_{k=1}^{\infty} \) is diagrammatically maximal, we may choose \( T_2 = W_{k,k} \) and \( K_2 = D(T_2) \) with \( k \) sufficiently large that

\[
\left| \frac{2\pi \log \det(K_2)}{c(K_2)} - v_{\text{oct}} \right| < \left( \frac{a + b}{b} \right) \frac{\epsilon}{2} \quad \text{and} \quad c(K_2) \geq c(\tilde{K}_1) \tag{5.2}
\]

The choice of \( K_2 \) ensures that the crossing numbers \( c(\tilde{K}_1) \) and \( c(K_2) \) satisfy the inequality

\[
k(k - 1) = c(K_2) \geq c(\tilde{K}_1) = \tilde{m} + 6 \tag{5.3}
\]

Let \( m = k(k - 1) - 6 \). Define \( T_1 = P_{3,m,3} \) and \( K_1 = D(T_1) \). This choice of \( m \) implies that

\[
c(K_1) = c(K_2)
\]

Using the fact that \( m \geq \tilde{m} \) we see that

\[
d_{\det}(K_1) = \frac{2\pi \log(6m + 9)}{m + 6} \leq \frac{2\pi \log(6\tilde{m} + 9)}{m + 6} < \left( \frac{a + b}{a} \right) \frac{\epsilon}{2} \tag{5.4}
\]

Let \( T \) be the tangle sum of \( a \) copies of \( T_1 \) with \( b \) copies of \( T_2 \), and let \( K = D(T) \) (see Figure 5.1). Then by Lemma 2.7 we have that \( \det(K) = (\det K_1)^a(\det K_2)^b \). Since \( T_1 \) and \( T_2 \) are strongly alternating.
tangles, we know from Corollary 2.15 that \( c(K) = a \cdot c(K_1) + b \cdot c(K_2) \). Therefore, we obtain the upper bound on \( d_{\text{det}}(K) \):

\[
d_{\text{det}}(K) = \frac{2\pi \log \det(K)}{c(K)} = \frac{2\pi \log((\det K_1)^a (\det K_2)^b)}{a \cdot c(K_1) + b \cdot c(K_2)}
\]

\[
= \frac{a}{a+b} \frac{2\pi \log \det(K_1)}{c(K_1)} + \frac{b}{a+b} \frac{2\pi \log \det(K_2)}{c(K_2)} \quad \text{by (5.5)}
\]

\[
< \frac{a}{a+b} \left( \frac{a+b}{a} \right) \epsilon + \frac{b}{a+b} \left[ \nu_{\text{oct}} + \left( \frac{a+b}{b} \right) \epsilon \right]
\]

\[
= \frac{b}{a+b} \nu_{\text{oct}} + \epsilon
\]

Now we obtain a lower bound on \( d_{\text{det}}(K) \):

\[
d_{\text{det}}(K) = \frac{a}{a+b} \frac{2\pi \log \det(K_1)}{c(K_1)} + \frac{b}{a+b} \frac{2\pi \log \det(K_2)}{c(K_2)} \quad \text{by (5.5)}
\]

\[
\geq \frac{b}{a+b} \frac{2\pi \log \det(K_2)}{c(K_2)}
\]

\[
> \frac{b}{a+b} \left( \nu_{\text{oct}} - \left( \frac{a+b}{b} \right) \epsilon \right) \quad \text{by (5.2)}
\]

\[
> \frac{b}{a+b} \nu_{\text{oct}} - \epsilon
\]

Note that the links constructed in the proof of Theorem 1.3 are not hyperbolic. It is interesting to study the relationship between \( \text{Spec}_{\text{det}} \) and \( \text{Spec}_{\text{vol}} \). Since \( \text{Spec}_{\text{vol}} \) considers only the densities of hyperbolic links, it is useful to know what determinant densities are realized by hyperbolic links. To this end, we have the following result.

**Theorem 5.3.** The set of determinant densities of hyperbolic links is dense in \([0, \nu_{\text{oct}}]\). In other words, given \( x \in [0, \nu_{\text{oct}}] \), and \( \epsilon > 0 \), there exists a hyperbolic link \( K \) such that \( |d_{\text{det}}(K) - x| < \epsilon \).

**Proof.** Let \( \epsilon > 0 \) be arbitrary, and let \( a \) and \( b \) be non-negative integers with \( a \) and \( b \) not both zero. Let \( W_{m,n} \) denote the reflection of the weaving tangle of Definition 3.2. Note that the sequence \( \{W_{\ell,\ell}\}_{\ell=1}^{\infty} \) is diagrammatically maximal by Theorem 2.4. Then by following an argument similar to the proof of Theorem 1.3 there exist integers \( k \) and \( \ell \) such that the link \( L = D(P_{3,k,3} + \ldots + P_{3,k,3} + W_{\ell,\ell} + \ldots + W_{\ell,\ell}) \), i.e. the denominator closure of the tangle sum of \( a \) copies of \( P_{3,k,3} \) with \( b \) copies of \( W_{\ell,\ell} \), satisfies

\[
|d_{\text{det}}(L) - \frac{b}{a+b} \nu_{\text{oct}}| < \frac{\epsilon}{2}
\]

Let \( T \) be the tangle obtained by the tangle sum of \( a \) copies of \( P_{3,k,3} \) with \( b \) copies of \( W_{\ell,\ell} \). For each positive integer \( m \), let \( K_m = N(T + \ldots + T) \) be the numerator closure of the tangle sum of \( m \) copies of \( T \), and let \( L_m = D(T + \ldots + T) \) be the denominator closure of this tangle sum. Note that \( T \) is prime, alternating, and not an east-west twist. Therefore Theorem 2.8 implies \( K_m \) is hyperbolic for \( m \geq 12 \). Moreover, the links \( K_m \) and \( L_m \) are reduced and alternating. Now the proof of [4] Theorem 1.7 implies that

\[
\lim_{m \to \infty} \frac{2\pi \log \det(K_m)}{c(K_m)} = \lim_{m \to \infty} \frac{2\pi \log \det(L_m)}{c(L_m)} = \lim_{m \to \infty} \frac{2\pi m \log \det(L_1)}{m \cdot c(L_1)} = d_{\text{det}}(L_1)
\]
Since $L_1 = L$, it follows that we may choose $m \geq 12$ sufficiently large that $|d_{\text{det}}(K_m) - d_{\text{det}}(L)| < \epsilon/2$. Since $\left| d_{\text{det}}(L) - \frac{b}{a+b} v_{\text{oct}} \right| < \frac{\epsilon}{2}$ by (5.6), it follows that

(5.8) \[ \left| d_{\text{det}}(K_m) - \frac{b}{a+b} v_{\text{oct}} \right| < \epsilon \]
