Abstract
The box–ball system is an integrable cellular automaton on a one-dimensional lattice. It arises from either quantum or classical integrable systems by procedures called crystallization and ultradiscretization, respectively. The double origin of the integrability has endowed the box–ball system with a variety of aspects related to Yang–Baxter integrable models in statistical mechanics, crystal base theory in quantum groups, combinatorial Bethe ansatz, geometric crystals, classical theory of solitons, tau functions, inverse scattering method, action-angle variables and invariant tori in completely integrable systems, spectral curves, tropical geometry and so forth. In this review, we demonstrate these integrable structures of the box–ball system and its generalizations based on the developments in the last two decades.

1. Introduction

1.1. The box–ball system

The box–ball system (BBS for short) is a cellular automaton introduced by Takahashi and Satsuma in 1990 [72]. It is a dynamical system of finitely many balls in an infinite number of boxes aligned on a line, whose time evolution is given by the following rule. We assume that each box can accommodate one ball at most.

(i) Move the leftmost ball to its nearest right empty box.
(ii) Move the leftmost ball among the rest to its nearest right empty box.
(iii) Repeat (ii) until all the balls are moved exactly once.

This defines an update corresponding to the one time step \( t \rightarrow t + 1 \). We remark that the above evolution rule is invertible. Let us show an example. By starting with the following configuration at time zero:

\[
\begin{array}{ccccccccc}
\bullet & \bullet & \bullet & & & & & & \\
\bullet & & & & & & & & \\
\end{array}
\]

we obtain the configuration at \( t = 1 \) as

\[
\begin{array}{ccccccccc}
\bullet & & & & & & & & \\
\bullet & \bullet & \bullet & & & & & & \\
\end{array}
\]

and so on:

\[
\begin{array}{ccccccccc}
\bullet & & & & & & & & \\
\bullet & \bullet & \bullet & & & & & & \\
\end{array}
\]

\[
\begin{array}{ccccccccc}
\bullet & \bullet & \bullet & & & & & & \\
\bullet & & & & & & & & \\
\end{array}
\]

\[
\begin{array}{ccccccccc}
\bullet & \bullet & \bullet & & & & & & \\
\bullet & & & & & & & & \\
\end{array}
\]

One observes that ‘a series of three balls’ and ‘a series of one ball’ proceed to the right stably unless they are ‘too close’ to each other. The larger one is faster than the smaller one, so they eventually collide. After the collision, it is non-trivial that they come back to their very original shape as \( 3 + 1 \rightarrow 1 + 3 \), instead of being smashed into pieces like \( 3 + 1 \rightarrow 1 + 1 + 1 + 1 \).
or getting glued together like $3 + 1 \rightarrow 4$. Moreover, the collision has caused a phase shift; observe that the trajectory of the larger (smaller) series has been shifted by 2 to the right (left).

Let us see another example:

| $t=0$ | $t=1$ | $t=2$ | $t=3$ | $t=4$ |
|-------|-------|-------|-------|-------|
| ⬤⬤⬤⬤ | ⬤⬤⬤⬤ | ⬤⬤⬤⬤ | ⬤⬤⬤⬤ | ⬤⬤⬤⬤ |

Here we have three series of 4, 3 and 1 balls from the left, and they are interchanged into the reverse order 1, 3 and 4 during $1 \leq t \leq 3$. These behaviors of a series of balls remind us of solitons in the theory of nonlinear waves. We call the number of balls in a series of balls before or after collisions an amplitude of the soliton. (A precise definition of solitons and their amplitude will be given later. See for example (2.47) or (3.22).)

One can also set up the BBS with the periodic boundary condition [82]. Let $L$ be the number of boxes aligned on an oriented circle. We put $M < L/2$ balls into them. The balls are moved by the same rule as the previous (i)–(iii) for the original (infinite) BBS except a minor adaptation to the fact that nothing can be ‘leftmost’ on a circle. In (i), the procedure can start from any chosen ball. In (ii), the terms ‘leftmost’ and ‘nearest right’ are to be understood along the direction of the orientation of the circle. Then, the modified evolution rule is well defined in the sense that the result is actually independent of the choice of the first ball to move. Moreover, it is again invertible. Let us look at an example of $L = 12$ and $M = 4$ in the following, where we identify the left and right boundaries (thick lines):

| $t=0$ | $t=1$ | $t=2$ | $t=3$ | $t=4$ | $t=5$ | $t=6$ |
|-------|-------|-------|-------|-------|-------|-------|
| ⬤⬤⬤⬤ | ⬤⬤⬤⬤ | ⬤⬤⬤⬤ | ⬤⬤⬤⬤ | ⬤⬤⬤⬤ | ⬤⬤⬤⬤ | ⬤⬤⬤⬤ |

One can observe that the larger soliton overtakes the smaller one repeatedly. The biggest difference from the infinite BBS is that the system now has a finite configuration space; there are just $\binom{12}{4}$ states. Thus, any state is cyclic, i.e. by starting with an arbitrary initial state, one comes back to itself in a finite time.

Let us motivate our study on the BBS from the viewpoint of solitons and integrability. Nowadays, the term soliton is widely used to mean, somewhat loosely, various special solutions to nonlinear equations that exhibit particle-like behavior or certain stability. In its original context of Zabusky and Kruskal [83], however, it meant a solitary wave solution
in an infinite-dimensional nonlinear dynamical system (Korteweg–de Vries (KdV) equation mentioned below) with more stringent properties as follows:

(a) particle-like propagation (constant velocity, stability under multi-body collision),
(b) factorization of scattering (pairwise scattering with phase shifts).

The existence of solitons is a signal of integrability, which at least postulates an infinite number of conserved quantities (integrals of motion). The historically important and famous integrable systems of such a kind are the KdV equation and the Kadomtsev–Petviashvili (KP) equation, which are prototypes of what is called a soliton equation. For finite-dimensional systems, the notion of integrability is clearer, i.e. it implies the existence of enough numbers of conserved quantities so that the initial value problem can be solved. The classic examples as Euler, Lagrange and Kovalevskaya tops belong to this category. We remark that the Toda equation is also an important dynamical system which is integrable either on finite or infinite lattices.

And so what about the BBS in which we have just observed ‘solitons’? Are they really solitons that possess the above-mentioned properties? Is the BBS really integrable in some sense? Is it related to integrable systems known hitherto? Is there any good mathematical framework to analyze it?

The aim of this review is to give an introductory exposition on a variety of aspects of the BBS elucidated in the last two decades, where all the above questions will be answered affirmatively.

1.2. Overview of related mathematics

It turns out that the BBS originates in a quantum integrable system as well as in a classical integrable system. It is located at the very special point where the two systems meet by the procedures called crystallization and ultradiscretization, respectively.

By quantum integrable systems, we mean those associated with the Yang–Baxter relation [6, 34]. Their symmetry is governed by the quantum group $U_q = U_q(\mathfrak{g})$ meaning the $q$-deformation of the universal enveloping algebra $U(\mathfrak{g})$ of some affine Lie algebra $\mathfrak{g}$ [11, 33]. Typical examples are solvable lattice models in statistical mechanics such as the six-vertex model [6] for $\mathfrak{g} = \hat{\mathfrak{sl}}_2$ and its generalizations. They are spin systems whose Boltzmann weights are continuous functions of $q$. The crystallization corresponds to taking the limit $q \to 0$, where the models are frozen to the ground state and its profile turns out to reproduce the BBS dynamics exactly.

By a classical integrable system we mean here integrable difference equations such as the discrete KP equation and (time-discretized versions of) the Lotka–Volterra equation, Toda equation and so forth. These equations are already defined on lattices (discrete spacetime), but their dynamical variables are yet continuous. The ultradiscretization is a procedure to transform these nonlinear evolution equations and their solutions into piecewise-linear forms. Leaving technical cautions aside, it is achieved by switching from the original variable $a$ to $A$ by $a = e^{-A/\varepsilon}$ and taking the limit $\varepsilon \to +0$. Being piecewise linear, the resulting equations allow one to restrict the dynamical variables to a certain discrete set. In this way, one reproduces evolution equations of the BBS and obtains their solutions.

Having double, classical as well as quantum, origins of integrability makes the study of the BBS especially rich. One can import a variety of notions and techniques to understand and analyze the BBS from the two theories. For instance, from the theory of quantum integrable systems, we have ingredients like the Yang–Baxter relation, quantum $R$ matrices, commuting transfer matrices, Bethe ansatz, corner transfer matrices and so forth [6, 20, 34, 45, 65, 73].
Similarly, the classical theory provides us with solitons, the inverse scattering method, tau functions, action-angle variables, isolevel set, spectral curves, linearization of flows, etc [1, 4, 5, 12, 15, 27, 59, 74]. It turns out that they all survive the crystallization or ultradiscretization rather miraculously. Moreover, they allow a systematic (Lie algebraic) generalization beyond the original BBS so that there are many kinds of balls or particles/anti-particles, boxes with capacity greater than 1, and a family of commuting time evolutions, etc. (Nonetheless, we will mainly focus on the basic type $\mathfrak{sl}_n + 1$ case in this review to be introductory.)

Compared with traditional integrable systems, certainly a novel feature of the BBS is that its dependent (or dynamical) variables have also been discretized. This fact indicates and actually has led to a fruitful connection to the realm of combinatorics. From a mathematical point of view, the crystallization and the ultradiscretization are both connected and actually have partly motivated the fascinating subjects known as the crystal base [38, 39] in the representation theory of a quantum group, geometric crystals [7] as its geometric counterpart and tropical geometry [58, 62] in algebraic geometry. As the title of this review suggests, it also contains elementary expositions and practical applications of these theories to the BBS.

Leaving the details to later sections, we present a rough schematic view of the relevant subjects as a summary:

| vertex model | $q \to 0$ | BBS | $0 \leftarrow \varepsilon$ | integrable difference equation |
| quantum group | $q \to 0$ | crystal base theory | $0 \leftarrow \varepsilon$ | geometric crystal |
| tropical geometry | $0 \leftarrow \varepsilon$ | algebraic geometry |

1.3. Contents

The main contents of each section are as follows: in section 2.1, the basic notion of crystallization is illustrated with the simplest vertex model of $U_q(\mathfrak{sl}_2)$. Section 2.2 is an exposition on $\mathfrak{sl}_{n+1}$ crystal base theory, which is applied to describe the infinite BBS in section 2.3. In section 2.4, we briefly sketch various generalizations of the BBS associated with affine Lie algebras. We remark that sections 2.2 and 2.3 are essential to study the BBS.

In section 3.1, the physical background of the Kerov–Kirillov–Reshetikhin (KKR) bijection in the Bethe ansatz is explained. The definition of the KKR bijection for the $\mathfrak{sl}_{n+1}$ crystal is given in section 3.2 with the concrete algorithm. In section 3.3, we state that the KKR bijection linearizes the time evolution of the BBS, which enables us to solve the initial value problem of the BBS.

In section 4.1, the notions of tropicalization, ultradiscretization and min–plus algebra are introduced. In section 4.2, two kinds of evolution equations for the BBS are provided, corresponding to the ‘spatial’ and ‘soliton’ descriptions of the BBS. The equations are the ultradiscretization of known integrable discrete systems. The first description is studied in sections 4.4 and 5.2, and the second one is studied in section 6.3. In section 4.3, we briefly explain the geometric crystal whose ultradiscretization gives the crystal structure. In section 4.4, the general solution for the BBS is given by the ultradiscrete tau function in a similar way to many soliton equations.

In section 5.1, the basic features of the periodic BBS are explained and its general solution is constructed via the (modified) KKR bijection in section 5.2. A remarkable feature is that the solution can be written in terms of tropical theta functions. In section 5.3, we discuss more details of the periodic BBS from the viewpoint of torus decomposition of the isolevel set and fundamental periods of the time evolution.
Section 6.1 is an introduction to tropical curve theory which is the latest mathematical object in this review. This theory is applied in section 6.2 to solve the tropical periodic Toda lattice (trop-pToda). In section 6.3, we show that the isolevel set of the periodic BBS is embedded in that of trop-pToda. This embedding bridges two different approaches to the periodic BBS by the trop-pToda and by the modified KKR bijection in section 5.2, from the viewpoint of the tropical geometric description of the isolevel sets.

We show a flowchart of the sections in this review:

```
2.4*  3.1*  
↑     ▼
2.1*  →  2.2  →  2.3  →  3.2  →  3.3  →  4.4  
↑     ▼
4.3*  5.1  →  5.2  →  5.3*
↑     ▼
4.1  →  4.2  →  6.1  →  6.2  →  6.3
```

where sections involving somewhat advanced or specialized topics are indicated by *.

We did not intend to make the reference list exhaustive. It is a moderate but sufficient supply for interested readers to proceed and find further references.

2. BBS and crystals

2.1. Crystallization: $q \to 0$ of the vertex model

For simplicity, we concentrate on the $U_q(\hat{sl}_2)$ case in this subsection. Let us recall the six-vertex model and its fusion. Consider the two-dimensional square lattice, where each edge is assigned with a local variable taking values in $\{1, 2\}$. Around each vertex, we allow the following six configurations with the respective Boltzmann weights:

\[
\begin{array}{cccccc}
1 & 1 & 1 & 2 & 2 & 2 \\
2 & 2 & 2 & 1 & 1 & 1 \\
1 & 1 & 2 & 2 & 1 & 1 \\
1 & 1 & 1 & 2 & 2 & 1 \\
\end{array}
\]

\[z \sum_{i < j} + \sum_{i > j} E_{ji} \otimes E_{ij},\]  

\[a(z) = 1 - q^2 z, \quad b(z) = q(1 - z), \quad c(z) = 1 - q^2.\]  

Here the indices run over $\{1, 2\}$ and $E_{ij}$ is the matrix unit acting as $E_{ij}v_k = \delta_{jk}v_i$. Schematically, (2.2) is expressed as
\( R(z) = \sum_{ijkl} (j \frac{i}{z}) E_{ij} \otimes E_{kl}, \quad \hat{R}(z) = \sum_{ijkl} (j \frac{i}{k}) E_{ij} \otimes E_{kl}, \) (2.3)

where the \( z \)-dependence is exhibited. The Yang–Baxter equation

\[
R_{23}(z') R_{13}(z) R_{12}(z/z') = R_{12}(z/z') R_{13}(z) R_{23}(z')
\]

holds [6], where the indices signify the components in the tensor product as \( V \otimes V \otimes V \) on which both sides act. It is depicted as

\[
\begin{array}{c}
\begin{array}{c}
\cdots \\
0
\end{array}
\end{array}
\quad = 
\begin{array}{c}
\begin{array}{c}
\cdots \\
0
\end{array}
\end{array}
\]

(2.4)

The \( R \) matrix \( R(z) \) is associated with the quantum affine \( U_q = U_q(\widehat{sl}_2) \) [11, 33]. There is an algebra homomorphism \( \Delta : U_q \to U_q \otimes U_q \) called the coproduct, which enables one to construct the tensor product representation \( V \otimes V' \) from any two representations \( V \) and \( V' \). Setting \( \hat{R}(z) := P \hat{R}(z) \) with \( P \) being the transposition of components, the quantum \( R \) matrix is characterized by the condition \( \Delta(x) R = R \Delta(x) \) for any \( x \in U_q \). The asymmetry between the last two in (2.1) is due to the special choice of the coproduct \( \Delta \) that suits the limit \( q \to 0 \) that will be considered in what follows. (The precise form of \( \Delta \) is not needed in this review.)

Starting from the six-vertex model, one can construct the multi-state (‘higher spin’) solvable vertex models by the fusion procedure [46]. Let \( V_m \) be the irreducible \( U_q \) module spanned by the \( m \)-fold \( q \)-symmetric tensors in \( V^{\otimes m} \). It is a \( q \)-analog of the spin-1 representation. Concretely, \( V_1 = V \) and \( V_m \) with \( m \geq 2 \) is realized as the quotient \( V^{\otimes m}/A \), where \( A = \sum_j V^{\otimes j} \otimes \text{Im} \hat{R}(q^{-2}) \otimes V^{\otimes m-2-j} \). It is easy to see \( \text{Im} \hat{R}(q^{-2}) = \text{Ker} \hat{R}(q^{-2}) = \mathbb{C}(v_1 \otimes v_2 - q v_2 \otimes v_1) \). We take the base vector of \( V_m \) as \( v_2^{x_2} \otimes v_1^{x_1} \bmod A \), where \( x_i \in \mathbb{Z}_{\geq 0} \) and \( x_1 + x_2 = m \). The base will also be denoted by \( x = (x_1, x_2) \) or by the sequence \( 1 \ldots 2 \ldots 2 \).

Obviously \( \dim V_m = m + 1 \). The outcome of the fusion procedure is the fusion \( R \) matrix \( R^{(m,1)}(z) \in \text{End}(V_m \otimes V_1) \) given by

\[
R^{(m,1)}(z)(x \otimes v_j) = \sum_{k=1,2} (j \frac{i}{k}) y \otimes v_k, \quad (2.5)
\]

\[
x \frac{i}{j} y = \begin{cases} 
q^{m-x_2} - q^{x_2+1} z & j = k, \\
(1 - q^{x_1}) z & (j, k) = (2, 1), \\
1 - q^{x_1} z & (j, k) = (1, 2),
\end{cases}
\]

(2.6)

where \( y = (y_1, y_2) \) is specified by the weight conservation (the so-called ice rule) as \( y_i = x_i + \delta_{ij} - \delta_{ik} \). The rhs of (2.6) is to be understood as 0 unless this condition is satisfied. For
For $m = 1$, one has $R^{(1,1)}(z) = R(z)$ and (2.6) reduces to (2.1). For $m = 2$, (2.6) reads explicitly as follows:

\[
\begin{align*}
    &1 & 1 & 1 & 1 & 2 & 1 & 1 & 2 & 1 & 1 & 1 & 1 \\
    &1 & 2 & 12 & 11 & 22 & 12 & 11 & 22 & 12 & 11 & 22 & 12 \\
    &1 - q^4z & 1 - q^2z & 1 - q^4z & q - q^2z & q^2 - qz \\
    &2 & 12 & 2 & 22 & 12 & 2 & 22 & 12 & 11 & 22 & 22 & 11 \\
    &1 - q^4z & (1 - q^2z) & 1 - q^2z & q^2 - qz & q - q^2z \\
\end{align*}
\]  

(2.7)

Here we have suppressed $z$ in the diagrams. Equation (2.7) is regarded as the (allowed) local configurations and their Boltzmann weights in a new vertex model where the horizontal and vertical edges take the three states $\{11, 12, 22\}$ and the two states $\{1, 2\}$, respectively. The weight conservation of $R^{(2,1)}(z)$ means that the total number of letters 1 and 2 are preserved from NW to SE.

Let us sketch how (2.7) is obtained from (2.1). The Yang–Baxter equation (2.4) with $z' = zq^2$ shows that $\text{Im} \tilde{R}(q^2) \subset V \otimes V$ is preserved under the action of $R_{13}(zq^2)R_{23}(z)$. Therefore, its action on $(V \otimes V) \otimes V$ can be restricted to $V_2 \otimes V_1 = ((V \otimes V)/\text{Im} \tilde{R}(q^2)) \otimes V$. This yields the $2 \times 1$ fusion leading to $R^{(2,1)}(z)$. Similarly, $R^{(m,1)}(z)$ can be deduced by restricting the composition $(a(z) \text{ defined in (2.2)})$

\[
\frac{R_{1,m+1}(zq^{m-1})R_{2,m+1}(zq^{m-3}) \cdots R_{m,m+1}(zq^{-m+1})}{a(zq^{m-3})a(zq^{m-5}) \cdots a(zq^{-m+1})}
\]  

(2.8)

to $V_m \otimes V_1$. One can furthermore fuse $R^{(m-1)}(z)$ along the other component of the tensor product in a completely parallel fashion. The result yields the quantum $R$ matrix $R^{(m,1)}(z) \in \text{End}(V_m \otimes V_l)$. The $R$ matrices so obtained again satisfy the Yang–Baxter equation in $\text{End}(V_l \otimes V_m \otimes V_1)$:

\[
R^{(m,k)}_{23}(z')R^{(l,k)}_{13}(z)R^{(l,m)}_{12}(z/z') = R^{(l,m)}_{12}(z/z')R^{(l,k)}_{13}(z)R^{(m,k)}_{23}(z').
\]  

(2.9)

It is depicted as (2.4) with the three lines to be interpreted as representing $V_l, V_m$ and $V_1$. The quantum $R$ matrix $R^{(m,1)}(z)$ gives rise to a fusion vertex model on a square lattice in a similar manner to (2.3) and (2.5). The local variables on the horizontal and vertical edges are taken from $V_m$ and $V_l$, respectively. In terms of the linear operator $\tilde{R}^{(m,1)}(z) := PR^{(m,1)}(z) : V_m \otimes V_l \to V_l \otimes V_m$, which is also called an $R$ matrix, the Yang–Baxter equation (2.9) takes another familiar form:

\[
(\tilde{R}^{(m,k)}(z') \otimes 1)(1 \otimes \tilde{R}^{(l,k)}(z))(\tilde{R}^{(l,m)}(z/z') \otimes 1) \\
= (1 \otimes \tilde{R}^{(l,m)}(z/z'))(\tilde{R}^{(l,k)}(z) \otimes 1)(1 \otimes \tilde{R}^{(m,k)}(z')).
\]  

(10)

It is $\tilde{R}^{(m,1)}(z)$ rather than $R^{(m,1)}(z)$ that will be directly related to the combinatorial or birational $R$ introduced in the later sections.

An important object in the vertex models is the (row to row) transfer matrix. For simplicity, we consider the basic case corresponding to $R^{(m,1)}(z)$. Then, the transfer matrix $T_m(z)$ is defined by
\[
T_m(z)(v_{j_1} \otimes \cdots \otimes v_{j_L}) = \sum_{\{k_i\}} \sum_{\{x^{(i)}\}} \left( \begin{array}{cccc}
\frac{j_1}{k_1} & \frac{j_2}{k_2} & \cdots & \frac{j_L}{k_L} \\
x^{(1)} & x^{(2)} & \cdots & x^{(L)}
\end{array} \right) v_{k_1} \otimes \cdots \otimes v_{k_L},
\]

(2.11)

where each \(k_i\) runs over \{1, 2\} and \(x^{(i)}\) does over the set of base of \(V_m\) labeled with \{1, 11, 1, 12, \ldots, 2, 22\}. The array of the vertex diagrams means the product of the corresponding Boltzmann weights (2.6). We have assumed that the (horizontal) length of the lattice is \(L\) and employed the periodic boundary condition. The transfer matrix allows one to express the partition function of the model (for \(\tilde{R}^{(m)}(z)\)) on \(N \times L\) lattice with the periodic boundary condition as \(Z = \text{Tr}(T_m(z)^N)\). All the matrices \(T_1(z), T_2(z), \ldots\) act on the same space \(V_1\). Using (2.9), one can show that they form a commuting family:

\[
T_m(z)T_1(w) = T_1(w)T_m(z).
\]

(2.12)

Now we are ready to discuss the main issue of the present section, namely the crystallization limit \(q \to 0\). In (2.7), we see that only the six configurations on the left three columns survive. In terms of the \(R\) matrix, the result may be stated that \(\tilde{R}^{(2,1)}(z)\) has the following action at \(q = 0\):

\[
11 \otimes 1 \mapsto 1 \otimes 11, \quad 12 \otimes 1 \mapsto 2 \otimes 11, \quad 22 \otimes 1 \mapsto 2 \otimes 12, \\
11 \otimes 2 \mapsto z(1 \otimes 12), \quad 12 \otimes 2 \mapsto z(1 \otimes 22), \quad 22 \otimes 2 \mapsto 2 \otimes 22.
\]

(2.13)

Here, \{11, 12, 22\} and \{1, 2\} are to be understood as labels of the bases of \(V_2\) and \(V_1\), respectively. Apart from the factor \(z\), (2.13) provides a bijection between the two sets. The same feature can be checked easily for the general \(m\) case (2.6). (It is immediately seen for \(m = 1\) by (2.1).) The configurations having non-vanishing matrix elements (Boltzmann weights) at \(q = 0\) are as follows:

\[
\begin{array}{c}
1 \ldots 1 \\
\vdots \\
1 \ldots 1 \\
\hline
x_1 & x_2 \\
\hline
1 & 2
\end{array}
\quad \begin{array}{c}
1 \ldots 1 \\
\vdots \\
1 \ldots 1 \\
\hline
x_1 & x_2 \\
\hline
1 & 2
\end{array}
\quad \begin{array}{c}
1 \ldots 1 \\
\vdots \\
1 \ldots 1 \\
\hline
x_1 & x_2 \\
\hline
2 & 2
\end{array}
\quad \begin{array}{c}
1 \ldots 1 \\
\vdots \\
1 \ldots 1 \\
\hline
x_1 & x_2 \\
\hline
2 & 2
\end{array}
\]

(0 \leq x_2 \leq m)

(0 < x_2 < m).

(2.14)

The limiting Boltzmann weights are all 1 except the bottom-right type, in which case it is \(z\). The configurations (2.14) determine a bijection between the data on the NW to SE, generalizing (2.13). In a physical terminology, the limit \(q \to 0\) corresponds to the low temperature limit, where crystallization takes place. Namely, spins are not allowed to thermally fluctuate and are frozen to the ground state configuration determined from their choice at the boundary of the lattice. Here is an example of such a configuration:

\[
\begin{array}{cccccccccccc}
1 & 2 & 2 & 2 & 2 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
111 & 111 & 112 & 122 & 222 & 122 & 222 & 122 & 112 & 111 & 111 & 111 \\
222 & 122 & 112 & 111 & 111 & 112 & 112 & 122 & 222 & 2 & 2 & 2
\end{array}
\]

(2.15)

Regard such a configuration on a two-dimensional lattice as a successive downward transfer of the horizontal array of spins on vertical edges. Then, each step is a deterministic map corresponding to the crystallization of the transfer matrix (2.11). Example (2.15) corresponds
to $T_j(1)$. This is an origin of the BBS time evolutions $T_1, T_2, \ldots$. The spins on the horizontal edges are "hidden variables" playing the role of carrier [71].

In the argument so far, one starts with $q$-dependent objects, e.g. fusion $R$-matrices and transfer matrices, and then consider their crystallization $q \to 0$. In the subsequent sections, we explain how such procedures can be simplified and even more systematized by invoking the crystal theory of the quantum group $U_q[38, 39, 28]$. It provides a general framework to set up everything at $q = 0$ from the outset. The labeling set of the bases of $V_m$ and the quantum $R$ matrix at $q = 0$ will be formulated as crystal and combinatorial $R$, respectively. The power of $z$ in (2.13) is called the energy (2.33), which will also play an important role. The BBS and its generalizations will be constructed as the canonical dynamical systems associated with the crystalline vertex models. We remark that a similar approach to the BBS by the crystallization of the quantum Lotka–Volterra lattice has been undertaken in [25].

2.2. Elements of crystal base theory

The theory of crystal bases was founded by Kashiwara [38, 39] as a representation theory of the quantum group $U_q$ at $q = 0$. The notion of crystal is abstracted from the theory of the crystal base [36]. In this subsection, we give a brief description of crystals and combinatorial $R$ which are basic ingredients in the BBS. We remark that the notion of a crystal lattice in the theory of crystal bases (see [28], for example) is omitted in this review, and our attention is focused on the notion of the crystal.

2.2.1. Definition of crystals. Let $I$ be an index set. A crystal $B$ is a set equipped with maps $\hat{e}_i, \hat{f}_i : B \to B \cup \{0\}$ for $i \in I$, satisfying certain axiom. In this review, we are exclusively concerned with the semiregular case of [28, definition 4.5.1]. Then, the relevant axiom is as follows.

- For any $b \in B$ and $i \in I$, there is $n > 0$ such that $\hat{e}_i^n b = \hat{f}_i^n b = 0$.
- $\hat{e}_0 = \hat{f}_0 = 0$.
- For $b_1, b_2 \in B$, $\hat{f}_i b_1 = b_2$ is equivalent to $\hat{e}_i b_2 = b_1$.

Here we have omitted the items in the axiom involving the weight $w t$ not used in this review. The $\hat{e}_i$ and $\hat{f}_i$ are called Kashiwara operators. They serve as $q = 0$ analogs of Chevalley generators. For $b \in B$, we set

$$\varepsilon_i(b) = \max\{m | (\hat{e}_i)^m(b) \neq 0\}, \quad \varphi_i(b) = \max\{m | (\hat{f}_i)^m(b) \neq 0\}. \quad (2.16)$$

For our construction of the BBS, we use the crystal $B_I$ associated with $\hat{s}_{n+1}$, where we take $I = \{0, 1, \ldots, n\}$ with $n \in \mathbb{Z}_{\geq 1}$. As a set, $B_I$ is given by

$$B_I = \left\{(x_1, \ldots, x_{n+1}) \in \mathbb{Z}^{n+1} \mid x_i \geq 0, \sum_{i=1}^{n+1} x_i = I \right\}. \quad (2.17)$$

The elements of $B_I$ are also represented by the Young tableaux. For each $x = (x_1, \ldots, x_{n+1}) \in B_I$, we associate a one-row semistandard tableau of length $l$ in which letter $i$ appears $x_i$ times. For instance, let $n = 2$ and $l = 2$. Then, the crystal

$$B_2 = \{(2, 0, 0), (0, 2, 0), (0, 0, 2), (1, 1, 0), (1, 0, 1), (0, 1, 1)\} \quad (2.18)$$
is also written as

$$B_2 = \{ \{1\}, \{1,2\}, \{1,3\}, \{2,3\}\}. \quad (2.19)$$

In what follows, all indices of $x_i, y_i, \ldots$ are interpreted in $\mathbb{Z}_{n+1} = \mathbb{Z}/(n+1)\mathbb{Z}$, namely $x_i + n + 1 = x_i$. The $B_l$ is the labeling set of the bases of the $l$-fold symmetric tensor representation (an example of the so-called Kirillov–Reshetikhin modules) of $U_q(\mathfrak{s\mathfrak{l}_n})$.

For $x = (x_1, \ldots, x_{n+1}) \in B_l$, let $\tilde{e}_i, \tilde{f}_i : B_l \to B_l \cup \{0\} \quad (0 \leq i \leq n)$ be maps defined by

$$\tilde{e}_i(x) = (\ldots, x_i + 1, x_{i+1} - 1, \ldots), \quad \tilde{f}_i(x) = (\ldots, x_i - 1, x_{i+1} + 1, \ldots). \quad (2.20)$$

if their images fall into $B_l$ or they are interpreted as 0 otherwise. According to (2.16), the maps $e_i, f_i : B_l \to \mathbb{Z}$ \quad (0 \leq i \leq n) are given by

$$e_i(x) = x_{i+1}, \quad f_i(x) = x_i. \quad (2.21)$$

For any crystals $B, B'$. one can define their tensor product $B \otimes B'$. As a set, it is a direct product $B \times B'$, but it also has a crystal structure. Any $(x, y) \in B \times B'$ determines an element $x \otimes y \in B \otimes B'$, and we understand $x \otimes 0 = 0 \otimes y = 0$. For $x \otimes y \in B \otimes B'$, the maps $e_i, f_i, \tilde{e}_i, \tilde{f}_i$ are given by

$$e_i(x \otimes y) = e_i(x) + (e_i(y) - f_i(y))_+, \quad (2.22)$$

$$f_i(x \otimes y) = f_i(y) + (f_i(x) - e_i(x))_+. \quad (2.23)$$

$$\tilde{e}_i(x \otimes y) = \begin{cases} \tilde{e}_i(x) \otimes y & \text{if } f_i(x) \geq e_i(y), \\ x \otimes \tilde{e}_i(y) & \text{if } f_i(x) < e_i(y), \end{cases} \quad (2.24)$$

$$\tilde{f}_i(x \otimes y) = \begin{cases} \tilde{f}_i(x) \otimes y & \text{if } f_i(x) > e_i(y), \\ x \otimes \tilde{f}_i(y) & \text{if } f_i(x) \leq e_i(y), \end{cases} \quad (2.25)$$

where $(x)_+ = \max(x, 0)$. The tensor product defined in this way satisfies the axioms of the crystals. By repeated use of this construction, one can define the tensor products of more than two crystals, where the (co)associativity $(B \otimes B') \otimes B'' = B \otimes (B' \otimes B'')$ holds. In particular, this allows one to define the $\mathfrak{s\mathfrak{l}_{n+1}}$ crystal $B_{l_1} \otimes \cdots \otimes B_{l_m}$ for any set of positive integers $l_1, \ldots, l_m$.

The crystals are represented by colored oriented graphs, known as *crystal graphs*. Let us show an example.

$$B_1 : \begin{array}{c} 1 \end{array} \begin{array}{c} \otimes \end{array} \begin{array}{c} 0 \end{array} \begin{array}{c} \rightarrow \end{array} \begin{array}{c} 2 \end{array} \quad \quad B_2 : \begin{array}{c} 111 \end{array} \begin{array}{c} \otimes \end{array} \begin{array}{c} 0 \end{array} \begin{array}{c} \rightarrow \end{array} \begin{array}{c} 12 \end{array} \begin{array}{c} \otimes \end{array} \begin{array}{c} 0 \end{array} \begin{array}{c} \rightarrow \end{array} \begin{array}{c} 22 \end{array} \quad (2.26)$$

Here the arrows with index $i$ represent the actions of $\tilde{f}_i$. A tensor product of crystals is represented as follows:

$$B_1 \otimes B_1 : \begin{array}{c} 1 \end{array} \begin{array}{c} \otimes \end{array} \begin{array}{c} 1 \end{array} \quad \begin{array}{c} 2 \end{array} \begin{array}{c} \otimes \end{array} \begin{array}{c} 1 \end{array} \quad \begin{array}{c} 2 \end{array} \begin{array}{c} \otimes \end{array} \begin{array}{c} 2 \end{array} \quad (2.27)$$
Let us show two more examples:

\[(2.28)\]

\[\begin{array}{c}
B_1 \otimes B_2 : \\
\begin{array}{c}
\begin{array}{c}
1 \otimes 1 | 1 \\
0 \otimes 1 | 1
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
1 \otimes 2 | 1 \\
0 \otimes 1 | 2
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
2 \otimes 1 | 2 \\
1 \otimes 2 | 2
\end{array}
\end{array}
\end{array}\]

\[(2.29)\]

\[\begin{array}{c}
B_2 \otimes B_1 : \\
\begin{array}{c}
\begin{array}{c}
1 \otimes 1 \otimes 1 \\
0 \otimes 1 \otimes 2
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
2 \otimes 2 | 1 \\
1 \otimes 2 | 2
\end{array}
\end{array}
\end{array}\]

2.2.2. Combinatorial R and its explicit formula. In general, two crystals \(B \otimes B'\) and \(B' \otimes B\) share a common crystal structure. The combinatorial \(R\) is the bijection between \(B \otimes B'\) and \(B' \otimes B\) that commutes with the actions of Kashiwara operators. It is a \(q \rightarrow 0\) limit of the quantum \(R\) matrix \(\hat{R}(z)\) in section 2.1. In other words, it is a map that commutes with the actions of \(K\) operators. It is a piecewise-linear formula for the combinatorial \(R\) which satisfies the following relations:

\[R(\tilde{c}_i(x \otimes y)) = \tilde{c}_i(R(x \otimes y)), \quad R(\tilde{f}_i(x \otimes y)) = \tilde{f}_i(R(x \otimes y)). \quad (2.30)\]

In all the cases we consider in this review, the combinatorial \(R\) is uniquely determined by demanding the above conditions.

By definition, the inversion relation \(R_{BB} \circ R_{B} = \text{Id}_{B \otimes B}\) holds. The simplest case is \(B = B'\), where the combinatorial \(R\) reduces to the identity map. As a non-trivial example, we find that the combinatorial \(R : B_2 \otimes B_1 \rightarrow B_1 \otimes B_2\) for \(\tilde{sl}_2\) is given by (2.13) by comparing the crystal graphs (2.28) and (2.29), modulo the power of \(z\) (which will be related to the energy function in (2.33)). For \(m\) general, \(R : B_m \otimes B_1 \rightarrow B_1 \otimes B_m\) for \(\tilde{sl}_2\) is given by (2.14) in the notation of (2.37). More generally, we will present a simple algorithm for \(R : B \otimes B' \rightarrow B' \otimes B\) in section 2.2.3.

For the \(\tilde{sl}_{m+1}\) crystals, there is a piecewise-linear formula for the combinatorial \(R\). Given \(x = (x_1, \ldots, x_{n+1}), y = (y_1, \ldots, y_{n+1}) \in \mathbb{Z}^{n+1}\), let \(\tilde{x} = (\tilde{x}_1, \ldots, \tilde{x}_{n+1}), \tilde{y} = (\tilde{y}_1, \ldots, \tilde{y}_{n+1}) \in \mathbb{Z}^{n+1}\) be defined by

\[\tilde{x}_i = x_i - P_i(x, y) + P_{i-1}(x, y), \quad \tilde{y}_i = y_i + P_i(x, y) - P_{i-1}(x, y),\]

\[P_i(x, y) = \max_{1 \leq k \leq n+1} \left( \sum_{j=k}^{n+1} x_{i+j} + \sum_{j=1}^{k} y_{i+j} \right). \quad (2.31)\]

**Proposition 2.1.** Given \(x \in B_i, y \in B_f\) define \(\tilde{x}, \tilde{y} \in \mathbb{Z}^{n+1}\) by (2.31). Then

(i) All their elements are non-negative; hence, \(\tilde{x} \in B_i, \tilde{y} \in B_f\).

(ii) Define \(R : B_i \otimes B_f \rightarrow B_f \otimes B_i\) by \(R(x \otimes y) = \tilde{y} \otimes \tilde{x}\). Then, it is the combinatorial \(R\) for the \(\tilde{sl}_{m+1}\) crystals, i.e. it satisfies relations (2.30).
One can prove it by showing the equivalence of the piecewise-linear formulas \((2.31)\) with an algorithm for the \(R\) in section 2.2.3 [21, proposition 4.1]. Another proof will be given, following an idea in [48, theorem 4.28], as a consequence of the corresponding assertion in geometric crystals (proposition 4.17).

The formula of the combinatorial \(R\) \((2.31)\) is characterized by the following relations:

\[
\begin{align*}
x_i + y_i &= \tilde{y}_i + \tilde{x}_i, \\
\max(-x_i, -y_{i+1}) &= \max(-\tilde{y}_i, -\tilde{x}_{i+1}),
\end{align*}
\]

\((2.32)\)

with an extra constraint \(\sum_{i=1}^{n+1} (x_i - \tilde{x}_i) = \sum_{i=1}^{n+1} (y_i - \tilde{y}_i) = 0\). Relations \((2.32)\) are a consequence of \(\epsilon_i(\tilde{y} \otimes \tilde{x}) = \epsilon_i(x \otimes y)\) and \(\psi_i(\tilde{y} \otimes \tilde{x}) = \psi_i(x \otimes y)\) which follow from \((2.30)\).

A notion related to the combinatorial \(R\) is the energy function \(H : B \otimes B' \rightarrow \mathbb{Z}\). For the \(s_{n+1}\) crystals, \(H : B_l \otimes B_r \rightarrow \mathbb{Z}\) is explicitly given by

\[
H(x \otimes y) = P_0(x, y) - \max(l, l').
\]

\((2.33)\)

Even if \(B = B'\) where we have \(R = Id\), the energy function is not trivial and plays an important role in the theory of crystals and their applications [36, 37]. For the BBS, \(H\) will be used in proposition 2.13.

2.2.3. Algorithm for combinatorial \(R\). There is a simple way to calculate the image of the combinatorial \(R\) and the energy function without drawing the whole crystal graph, due to Nakayashiki and Yamada [60]. We explain the algorithm along with an example:

\[
R \left( \begin{array}{c}
1 \\
3 \\
3 \\
4 \\
7 \\
\otimes \\
1 \\
3 \\
\end{array} \right) \otimes \left( \begin{array}{c}
1 \\
3 \\
3 \\
5 \\
\end{array} \right) = \left( \begin{array}{c}
1 \\
4 \\
7 \\
\otimes \\
1 \\
3 \\
3 \\
5 \\
\end{array} \right).
\]

\((2.34)\)

Given the left-hand side, we can obtain the right-hand side by using the following diagram:

We suppose \(l \geq l'\) but to guess the algorithm in the case \(l < l'\) is easy. Represent \(x = (x_1, \ldots, x_{n+1}) \in B_l\) by a pile of \(n + 1\) boxes in which there are \(x_i\) dots in the \(i\)th highest box. Do the similar for \(y = (y_1, \ldots, y_{n+1}) \in B_r\) and then juxtapose these piles of boxes. Repeat the following procedure (1)–(3) to obtain \(l'\) pairs of connected dots. (All the dots are unconnected initially.) (1) Choose any unconnected dot \(A\) in the right pile. (2) Look for its partner \(B\) in the left pile which is an unconnected dot in the lowest position but higher than that of \(A\). If there is no such dot, \(B\) is chosen among unconnected dots in the lowest position. (We call the former case unwinding and the latter winding.) (3) Connect \(A\) and \(B\). At the end, we transfer all the unconnected dots from the left pile to the right one horizontally, yielding the piles for \(R(x \otimes y)\). The energy function \((2.33)\) is given by

\[
H(x \otimes y) = \#(\text{winding pairs}).
\]

\((2.35)\)

For the above example \((2.34)\), we have \(H(x \otimes y) = P_0(x, y) - \max(l, l') = 6 - 5 = 1\).

The algorithm for \(R\) and \(H\) will serve as the most substantial tool to check the examples in sections 2.2.4 and 2.3.

2.2.4. Yang–Baxter equation. The most important property of the combinatorial \(R\) is

\textbf{Proposition 2.2.} The following relation holds on \(B \otimes B' \otimes B'':\)

\[
(R \otimes 1)(1 \otimes R)(R \otimes 1) = (1 \otimes R)(R \otimes 1)(1 \otimes R).
\]

\((2.36)\)
Relation (2.36) is known as the Yang–Baxter equation. We depict the relation \( R(x \otimes y) = \tilde{y} \otimes \tilde{x} \) by

\[
\begin{array}{c}
\tilde{y} \\
\tilde{x}
\end{array}
\quad
\begin{array}{c}
x \\
y
\end{array}
\]

\[ (2.37) \]

**Example 2.3.** By using the algorithm in section 2.2.3, one can observe that the maps on both sides of (2.36) send an element in \( B_6 \otimes B_3 \otimes B_1 \) to the same element in \( B_1 \otimes B_3 \otimes B_6 \):

\[
\begin{align*}
(R \otimes 1)(1 \otimes R)(R \otimes 1)\left( \begin{array}{c}
2 & 2 & 3 & 4 & 5 & 5 \\
3 & 3 & 4 & 4 & 5 & 6
\end{array} \right)
&= (R \otimes 1)(1 \otimes R)\left( \begin{array}{c}
2 & 2 & 3 \\
3 & 3 & 4 & 4 & 5 & 5 & 6
\end{array} \right) \\
&= (R \otimes 1)\left( \begin{array}{c}
2 & 2 & 5 \\
3 & 3 & 4 & 4 & 5 & 6
\end{array} \right)
\end{align*}
\]

\[
\begin{align*}
(1 \otimes R)(R \otimes 1)(1 \otimes R)\left( \begin{array}{c}
2 & 2 & 3 & 4 & 5 & 5 \\
3 & 3 & 4 & 6
\end{array} \right)
&= (1 \otimes R)(R \otimes 1)\left( \begin{array}{c}
2 & 2 & 3 & 4 & 5 & 5 \\
4 & 3 & 3 & 6
\end{array} \right) \\
&= (1 \otimes R)\left( \begin{array}{c}
3 \\
2 & 2 & 4 & 4 & 5 & 5
\end{array} \right)
\end{align*}
\]

\[
\begin{align*}
&= (1 \otimes R)\left( \begin{array}{c}
3 \\
2 & 2 & 5 \\
3 & 3 & 4 & 4 & 5 & 6
\end{array} \right)
\end{align*}
\]

It is also depicted as the following diagrams, where the lines represent crystals and their crossings stand for the combinatorial Rs (see (2.37)):

\[
\begin{align*}
223455 & \quad \quad 334 \\
334455 & \quad \quad 6
\end{align*}
\]

**2.3. Basic features of the BBS**

In this section, we introduce a one-dimensional cellular automaton associated with \( \widehat{\mathfrak{sl}}_{n+1} \) crystals. For a more extensive presentation, see [68].

**2.3.1. States and time evolutions.** For any positive integer \( L \), we define a dynamical system on \((B_1)^{\otimes L}\) which generalizes the BBS in section 1. In this system, one may regard \( \begin{array}{c} \alpha \end{array} \in B_1 \) (\( \alpha > 1 \)) as a box of capacity 1 containing a ball with color \( \alpha \) inside it, and \( \begin{array}{c} 1 \end{array} \in B_1 \) as an empty box of capacity 1. We call our dynamical system an \( \widehat{\mathfrak{sl}}_{n+1} \) BBS. It is a cellular automaton equipped with a family of commuting time evolutions \( T_1, T_2, \ldots \) defined in what follows.
Let $R : B_l \otimes B_l \rightarrow B_l \otimes B_l$ be the combinatorial $R$ and define $R_i = \Id \otimes \cdots \otimes \Id \otimes R \otimes \Id \otimes \cdots \otimes \Id \ (1 \leq i \leq L)$, which is a map from $(B_l)^{\otimes i-1} \otimes B_l \otimes (B_l)^{\otimes L-i+1}$ to $(B_l)^{\otimes i} \otimes B_l \otimes (B_l)^{\otimes L-i}$. Then, $R = R_l \circ \cdots \circ R_1$ is a map from $B_l \otimes (B_l)^{\otimes L}$ to $(B_l)^{\otimes L} \otimes B_l$. Given an arbitrary $v \otimes b_1 \otimes \cdots \otimes b_L \in B_l \otimes (B_l)^{\otimes L}$, let $R(v \otimes b_1 \otimes \cdots \otimes b_L) = b'_1 \otimes \cdots \otimes b'_L \otimes v'$. It is depicted by

$$v \begin{array}{c|c|c|c|c|c|c|c} b_1 & b_2 & \cdots & b_{L-1} & b_L \hline b'_1 & b'_2 & \cdots & b'_{L-1} & b'_L \end{array} \begin{array}{c|c} \vdots \hline \vdots \end{array} \begin{array}{c|c} v_{L-1} \hline v' \end{array}$$

(2.39)

or simply by

$$v \begin{array}{c|c|c|c|c|c|c|c} b_1 & b_2 & \cdots & b_{L-1} & b_L \hline b'_1 & b'_2 & \cdots & b'_{L-1} & b'_L \end{array} \begin{array}{c|c} \vdots \hline \vdots \end{array} \begin{array}{c|c} v_{L-1} \hline v' \end{array}.$$  

(2.40)

We assume that the conditions

$$L \gg 1, \quad b_i = \mathbb{1} \quad \text{for all } i \gg 1,$$

(2.41)

are satisfied in (2.39), and take

$$v = u_l := \begin{array}{c|c|c} \mathbb{1} & \mathbb{1} & \mathbb{1} \end{array}.$$  

(2.42)

Then, we have $v' = u_l$ and the set $\{b'_1, \ldots, b'_L\}$ coincides with $\{b_1, \ldots, b_L\}$ as a set but the order of its elements gets shuffled. Under this setting let $T_l : (B_l)^{\otimes L} \rightarrow (B_l)^{\otimes L}$ and $E_l : (B_l)^{\otimes L} \rightarrow \mathbb{Z}$ be the maps given by

$$T_l(b_1 \otimes \cdots \otimes b_L) = b'_1 \otimes \cdots \otimes b'_L,$$

(2.43)

$$E_l(b_1 \otimes \cdots \otimes b_L) = \sum_{i=1}^{L} (1 - H(v_{i-1} \otimes b_i)), $$

(2.44)

where $v_0 = v$. Call $T_l$ the $l$th time evolution and $E_l$ the $l$th energy. We note that every summand of (2.44) vanishes for $i \gg 1$ because of $H(u_l \otimes \mathbb{1}) = 1$, which ensures the convergence of the energy in the limit $L \rightarrow \infty$.

In what follows, we often use the symbol $\simeq$ to indicate that its two sides are transformed to each other by the isomorphism (composition of combinatorial $R$s) of crystals. For instance, the relation (2.37) is expressed as $x \otimes y \simeq \hat{y} \otimes \hat{x}$. This notation allows one to write relation (2.43) as a crystal version of ‘Lax equation’

$$u_l \otimes p \simeq T_l(p) \otimes u_l,$$

(2.45)

where $p = b_1 \otimes \cdots \otimes b_L$. An element in $B_l$ is regarded as a carrier which can carry at most $l$ balls. (The notion of carrier was introduced in [71] in the case of $\mathfrak{sl}_2$.) In the carrier $x = (x_1, \ldots, x_{l+1}) \in B_l$, the count of balls with label $i \geq 1$ is $x_i$. The $u_l (2.42)$ corresponds to a vacant carrier. In (2.39), a carrier runs from left to right, changing itself as $v \rightarrow v_1 \rightarrow v_2 \rightarrow \cdots$. Although it is nothing but a repeated use of the algorithm in section 2.2.3 with $l' = 1$, one can regard it as a successive loading/unloading process of balls into/out of the carrier.

To illustrate how the carrier works, as well as how the energy (2.44) is evaluated, we show a few examples for (2.39).
Example 2.4. Carriers with capacity 4, 3 and 2. Consider the state at $t = 3$ in example 2.11 below. By the time evolution $T_4$, it evolves into the state at $t = 4$ as follows:

\[
\begin{array}{cccccccc}
1111 & 1112 & 1122 & 1222 & 2222 & 1222 & 1122 & 1222 \\
1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
\end{array}
\]

We added \( \bullet \) to each vertex which scores $+1$ to the energy (2.44). Assuming that there are only 1s to the right of the first row, there are no more scoring vertices. Hence, we have $E_4 = 9$. At the vertex with \( \bullet \), no winding pairs occur in the algorithm in section 2.2.3 which makes the value of the energy function (2.35) zero.

If the state were evolved by $T_3$, then the diagram would be as follows:

\[
\begin{array}{cccccccc}
1111 & 1112 & 1122 & 2222 & 1222 & 1122 & 1222 & 1122 \\
1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
\end{array}
\]

Hence, $E_3 = 8$. In the same way, $T_2$ would change the state as follows:

\[
\begin{array}{cccccccc}
1111 & 1112 & 1222 & 2222 & 1222 & 1222 & 1222 & 1222 \\
1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
\end{array}
\]

Hence, $E_2 = 6$. It is easy to see $E_1 = 3$ and $E_l = 9$ for $l \geq 4$.

Based on the Yang–Baxter equation (2.36), one can prove the commutativity of the time evolutions and the conservation of the energy.

**Proposition 2.5** [17, theorem 3.2]. The following relations are satisfied:

\[ T_l T_{l'}(p) = T_{l'} T_l(p), \quad E_l(T_{l'}(p)) = E_{l'}(p), \]

for any $l, l' \geq 1$ and state $p = b_1 \otimes \cdots \otimes b_L$.

The $l$th energy $E_l$ is the conserved quantity associated with the time evolution $T_l$. Under conditions (2.41), we define $T_\infty$ just by taking a formal limit $l \to \infty$ in (2.45). In fact, $T_l(p) = T_\infty(p)$ holds if and only if $l$ is greater than or equal to the maximum amplitude of the solitons contained in $p$. (This is due to theorem 3.7, especially (3.19). See (2.47) for how to determine the amplitudes of solitons.) Remark that $T_1$ serves as a shift operator which moves every ball to its right adjacent box.

Time evolutions of a state will be illustrated by drawing $T_l^i(p)$, $T_l^{i+1}(p)$, $T_l^{i+2}(p)$, \ldots downward. For a state $T_l^i(p) = d_1^l \otimes \cdots \otimes d_L^l$, we omit the symbol $\otimes$ and write it as $d_1^l \ldots d_L^l$. Hence, $d_i^l$ denotes the value at site $i$ and time $t$. In what follows, we write $d_i^l = \cdot$ (a dot) instead of $d_i^l = 1$ for simplicity. Here is an example of the time evolution under $T_\infty$:

\[
\begin{array}{cccccccc}
t=3 & 322554433 & . & . & . & . & . & . \\
\end{array}
\]

\[
\begin{array}{cccccccc}
t=4 & 322 & . & 5564433 & . & . & . & . \\
\end{array}
\]

\[
\begin{array}{cccccccc}
t=5 & 322 & . & 5 & . & 654433 & . & . \\
\end{array}
\]

The special time evolution $T_\infty$ admits an elementary algorithm due to Takahashi [70] generalizing the $sl_2$ case in section 1, which is a (non-local) description without a carrier.
Proposition 2.6. $T_\infty = K_2 K_3 \cdots K_{n+1}$ where $K_a$ is an operator that works as follows.

1. Exchange the leftmost $[a]$ with its nearest right $[1]$.
2. Exchange the leftmost $[a]$ among the rest of the $[a]$ with its nearest right $[1]$.
3. Repeat (ii) until all of the $[a]$ are moved exactly once.

Example 2.7. We apply $T_\infty = K_2 K_3 K_4 K_5$ to the $t=4$ state in example 2.15 to obtain the $t=5$ state.

| $t=4$ | $t=5$ |
|-------|-------|
| 322...556433 | 322...554433...65433 |
| 322...554433...65 | 322...554433...65433 |
| 322...554336 | 322...554336...65433 |
| 322...55...336544 | 322...55...65433 |
| 322...5...336544 | 322...5...65433 |
| 223...5...654433 | 322...5...65433 |

A comparison of our formalism of the BBS with that of the vertex models is summarized in the following table.

| | Vertex models | BBS |
|---|---|---|
| Local states | $U_q$-module | Crystal |
| Local interaction | Quantum $R$ | Combinatorial $R$ |
| $T_l$ | Transfer matrix | Time evolution |

2.3.2. Solitons. Now we define solitons in the BBS. Intuitively, a pattern like $i_l \cdots i_1$ satisfying the condition $i_l \geq \cdots \geq i_1 > 1$ can be regarded as a soliton of amplitude $l$. It is denoted by $[i_l \cdots i_1]$. In examples 2.8 and 2.9 below, the sequence 554322 is a soliton of amplitude 6.

Example 2.8. Time evolution by $T_l$ with $l \geq 6$:

| $t=0$ | $t=1$ | $t=2$ |
|-------|-------|-------|
| 554322 | 554322 | 554322 |
| 554322 | 554322 | 554322 |

Example 2.9. Time evolution by $T_k$:

| $t=0$ | $t=1$ | $t=2$ |
|-------|-------|-------|
| 554322 | 554322 | 554322 |
| 554322 | 554322 | 554322 |

If well separated from the others, a soliton of amplitude $l$ travels at a speed of $\min(l, k)$ under the time evolution $T_k$. In particular, we have the following for any 1-soliton state:

Proposition 2.10 [17, lemma 4.1]. If there exists only one soliton in the state, it travels at a speed of $\min(l, k)$ under the time evolution $T_k$ where $l$ is the amplitude of the soliton. And the value of the associated energy $E_k$ is also given by $\min(l, k)$.

Under the intuitive definition of solitons, one observes that the number of solitons of each amplitude may look changing during their scattering processes. We rather want to treat solitons as conserved quantities in the BBS. For this purpose, we define $m_l$ by

$$E_l = \sum_{k \geq 1} \min(l, k)m_k \quad \text{or equivalently} \quad m_l = -E_{l-1} + 2E_l - E_{l+1}, \quad (2.47)$$

where $E_0 = 0$ is understood. Since $E_l$s are conserved quantities, so are $m_l$s. Then, one can interpret $m_l$ as the number of solitons of amplitude $l$. In view of proposition 2.10, it is consistent
with the previous definition of solitons in the case where solitons are well separated. By the
definition, any state \( p \) is an \( N \)-soliton state, where \( N \) is determined by \( N = E_l(p) \). We note that
according to (2.42), \( E_l(p) \) equals the number of adjacent pairs \( \{1 \otimes a \} \) with \( a > 1 \) appearing
in \( p \), whereas \( E_\infty(p) \) is the total number of balls.

**Example 2.11.** A three-body scattering process under \( T_\infty \). From example 2.4, we find at \( t = 3 \)
that \( m_l = -E_{l-1} + 2E_l - E_{l+1} = 1 \) for \( l = 2, 3, 4 \) and \( m_l = 0 \) in the other cases.

\[
\begin{align*}
\text{t=0} & \quad 554322. \quad 422. \quad \ldots \\
\text{t=1} & \quad 554322. \quad 422. \quad \ldots \\
\text{t=2} & \quad 554322. \quad 422. \quad \ldots \\
\text{t=3} & \quad 554322. \quad 422. \quad \ldots \\
\text{t=4} & \quad 554322. \quad 422. \quad \ldots \\
\text{t=5} & \quad 553. \quad 442222. \quad \ldots \\
\text{t=6} & \quad 553. \quad 442222. \quad \ldots \\
\text{t=7} & \quad 553. \quad 442222. \quad \ldots \\
\end{align*}
\]

We will see that the nonlinear time evolutions of the BBS are transformed into linear ones on
the rigged configurations. See example 3.8.

We remark that, besides \( m_l \)s, our BBS has additional conserved quantities (3.20). By
using the crystals for anti-symmetric representations, one can show that the color degrees of
freedom for any state of the BBS can be transformed into a ‘word’ which does not change
under any \( T_l \) [67].

2.3.3. **Scattering rules.** The scattering of solitons in our BBS consists of the exchange of
their internal degrees of freedom and the phase shifts. Although it is possible to treat general
many-body scattering processes, we devote ourselves to the case of two-body scatterings for
simplicity. In what follows, we assume that the time evolution is given by \( T_\infty \).

**Example 2.12.** A scattering process of two solitons with amplitudes \( l = 6 \) and \( l' = 3 \) in \( \bar{A}_5 \)

\[
\begin{align*}
\text{t=0} & \quad 554322. \quad 422. \quad \ldots \\
\text{t=1} & \quad 554322. \quad 422. \quad \ldots \\
\text{t=2} & \quad 554322. \quad 422. \quad \ldots \\
\text{t=3} & \quad 554322. \quad 422. \quad \ldots \\
\text{t=4} & \quad 554322. \quad 422. \quad \ldots \\
\text{t=5} & \quad 553. \quad 442222. \quad \ldots \\
\text{t=6} & \quad 553. \quad 442222. \quad \ldots \\
\text{t=7} & \quad 553. \quad 442222. \quad \ldots \\
\end{align*}
\]

Suppose at time \( t = 0 \), the state bears two solitons \([i_1 \ldots i_1] \) and \([j_1 \ldots j_1] \). Denote this
two-soliton state by \([i_1 \ldots i_1] \times [j_1 \ldots j_1] \), where \( x \) and \( y \) are the positions of their leftmost
letters. For instance, we have \([554322] \times [422] \) in example 2.12 at \( t = 0 \). We assume
\( l > l' \) and \( x \ll y \). Then, the former catches up with the latter and they eventually collide.
Before the collision, these solitons travel at speeds of \( l \) and \( l' \) cells per unit time, respectively,
so at time \( t \) we have \([i_1 \ldots i_1]_{x+lt} \times [j_1 \ldots j_1]_{y+l't} \). After the collision, we have a two-soliton
state \([j_1 \ldots j_1]_{y+l't-\delta} \times [\tilde{i}_1 \ldots \tilde{i}_1]_{x+lt+\delta} \) where \( \delta \) is a phase shift. (This fact is also a part
of the statements in the forthcoming proposition 2.13.) By the collision, the larger soliton gets
pushed forward and the smaller soliton pulled backward by an amount of \( \delta \) cells.

The exchange of the internal degrees of freedom occurring here is governed by the
combinatorial \( R \), and the phase shift is essentially given by the energy function \( H \).
Proposition 2.13 [17, theorem 4.6]. Any collisions of two solitons asymptotically break up into two solitons. Let the two-soliton state be \([i_1 \ldots i_l]_t \times [j_{l'} \ldots j_{l''}]_t\) at time \(t\) well before the collision, and \([j_{l'} \ldots j_{l''}]_{t+\delta t} \times [i_1 \ldots i_l]_{t+\delta t}\) for \(t\) after the collision. Then, the phase shift \(\delta\) is given by
\[
\delta = H \left( [j_{l''}]_t \otimes [i_1]_t \right) + l'.
\]

And the exchange of the internal degrees of freedom is described by the combinatorial \(R\) for the \(\hat{s}_n\) crystals\(^4\)
\[
R \left( [i_1]_t \otimes [j_1]_t \right) = [\tilde{j}_1]_{t-\delta} \otimes [\tilde{i}_1]_t.
\]

The phase shift can be computed by (2.33) or (2.35). It is always positive and take values between \(l'\) and \(2l'\).

Example 2.14. The scattering process in example 2.12 is expressed as \([554322]_t \times [422]_{t+3} \rightarrow [553]_t \times [44222]_{t+6}\). This is described by the combinatorial \(R\) for the \(\hat{s}_4\) crystals. By using the algorithm in section 2.2.3, it can be computed as

\[
\text{The value of the energy function (\(= \# \text{ (winding pairs)}\)) is 2 and we observe that the phase shift is given by } \delta = 2 + 3 = 5.
\]

Example 2.15. Scattering processes of three solitons. There are three solitons \([554322], [433], [6]\) at time \(t = 0\), and again three solitons \([3], [522], [654433]\) at time \(t = 8\).

The elements of crystals that appeared in the formulas in proposition 2.13 have no letter ‘1’. Hence, the combinatorial \(R\) and the energy function used there are regarded as those for \(\hat{s}_n\) crystals by reducing the value of all letters in the Young tableaux by 1.
Both processes have the same kinds of solitons at \( t = 0 \). The orders of collisions occurring in subsequent times are different. The fact that the outcomes at \( t = 8 \) share a common soliton content can be viewed as a consequence of the Yang–Baxter equation (2.36). See example 2.3.

Due to the commutativity of the time evolutions (proposition 2.5), the scattering rule remains unchanged when \( T_\infty \) is replaced by \( T_k \) for any \( k > 1 \). In this case, we have the two-body scattering \( [i_1 \ldots i_l]_{k+\min(k,l)} \times [j_1 \ldots j_l]_{k+\min(k,l)} \rightarrow [j_1 \ldots j_l]_{k+\min(k,l)} \times [i_1 \ldots i_l]_{k+\min(k,l)} \). Here the phase shift and exchange of internal degrees of freedom are still given by (2.48) and (2.49).

### 2.3.4. \( s_{ln} \) symmetry

So far we have not mentioned the role of the Kashiwara operators acting on the states of the BBS. Their significance is recognized as the \( s_{ln} \) symmetry in the system. Let \( p \) be a state of the BBS. Suppose \( \dot{e}_i p \neq 0 \) for some \( i \in \{2, \ldots, n\} \). Then, we have

\[
T_i(\dot{e}_i p) = \dot{e}_i T_i(p), \quad E_i(\dot{e}_i p) = E_i(p)
\]

for any \( i \) [17]. The first relation is a manifestation of the \( s_{ln} \) symmetry of the time evolution. Due to (2.47) and the second relation in (2.50), this transformation does not change the amplitudes of solitons but alters their internal labels.

A conserved quantity associated with the \( s_{ln} \) symmetry is defined as follows. Given a state \( p = [a_1] \otimes \cdots \otimes [a_l] \), let \( w_1 \ldots w_k \) be the word which is obtained from \( a_1 \ldots a_l \) by ignoring every 1. Denote by \( P(p) \) the \( P \)-symbol \( P(w_k \ldots w_1) \) and \( Q(p) \) the \( Q \)-symbol \( Q(w_k \ldots w_1) \) (semi-standard Young tableaux) obtained from the opposite word \( w_k \ldots w_1 \) by the Robinson–Schensted–Knuth correspondence [18]. Explicitly the \( P \)-symbol is defined as

\[
P(w_k \ldots w_1) = w_k \rightarrow (w_{k-1} \rightarrow (\ldots (w_3 \rightarrow (w_2 \rightarrow w_1)) \ldots))
\]

where \( \rightarrow \) implies the column insertion and \( \leftarrow \) does the row insertion [18]. The \( Q \)-symbol is the standard tableau consisting of \( \{1, \ldots, k\} \) that records the growth history of the \( P \)-symbol.

We have the following:

**Proposition 2.16** [16, theorem 3.1]. The \( P \)-symbol \( P(p) \) is a conserved quantity of the BBS, i.e. \( P(T_i(p)) \) is independent of \( t \) for any \( i \).

We note that the time evolution of the BBS is attributed to the dynamics of the \( Q \)-symbol [16, theorem 5.1].

For instance, consider example 2.15. The opposite words \( w_{10} \ldots w_1 \) are 6334223455 for \( t = 0 \) and 3344562253 for \( t = 8 \). Both words share a common \( P \)-symbol

\[
P(T_{10}(p)) = \frac{223455}{334} \text{.}
\]

The growth pattern of the pair \( (P, Q) \) by the successive row insertions for the word 6334223455 looks as follows:

\[
\begin{array}{cccccccc}
6 & 1 & 3 & 1 & 33 & 13 & 334 & 134 \\
234 & 134 & 224 & 134 & 223 & 134 \\
3 & 2 & 33 & 26 & 334 & 267 \\
6 & 5 & 6 & 5 & 6 & 5 \\
2234 & 1348 & 22345 & 13489 & 223455 & 13489X \\
334 & 267 & 334 & 267 & 334 & 267 \\
6 & 5 & 6 & 5 & 6 & 5
\end{array}
\]

Here \( X \) denotes 10.
In the case of $sl_2$ it is known that one can introduce another $P$-symbol whose shape, which represents the list of amplitudes of solitons, is a conserved quantity [2, 78].

2.4. Various generalizations

The BBS has been generalized extensively. Here we present a few prototype examples.

• Generalizations in the $\hat{sl}_{n+1}$ case. The original BBS consists of boxes with capacity 1 only, which corresponds to the fact that the states belong to $\cdots \otimes B_1 \otimes B_1 \otimes \cdots$. A natural generalization is to replace it with $\cdots \otimes B_i \otimes B_{k_i} \otimes \cdots \otimes \cdots$. The commuting family of time evolutions $\{T_i\}$ are defined in the same way as before, where the vertical lines in (2.40) now represent $B_{k_i}$'s. The resulting dynamical system is BBS involving a box with capacity $k_i$ at the site $i$ [21, 76]. The basic features of the system, e.g. solitons, scattering rules, conserved quantities, linearization scheme, etc, remain the same as the capacity 1 case. See [21, 49, 53]. The BBS with a periodic boundary condition will be treated in section 5.

One can further use crystals other than the family $[B_i]$. Examples of such kind are a BBS with the reflecting end [52] and a BBS associated with an anti-symmetric tensor representations of $U_q(\hat{sl}_{n+1})$ [80].

• $\check{g}_n$-automaton. Similarly to the $\hat{sl}_{n+1}$ case, integrable cellular automata associated with the non-exceptional affine Lie algebra $\check{g}_n = B_n^{(1)}, C_n^{(1)}, D_n^{(1)}, A_{2n-1}^{(2)}, A_{2n}^{(2)}$ and $D_{2n+1}^{(2)}$ have been constructed [24] and the soliton scattering rule determined [23]. The dynamics allows for a neat description in terms of particles and anti-particles that undergo pair creations and annihilations [22]. The BBS turns out to be the special case in which no anti-particle is present. Let us demonstrate the $D_4^{(1)}$ case. Each local state takes values in $\{1, 2, 3, 4, \bar{1}, \bar{2}, \bar{3}, \bar{4}\}$, where $\bar{2}, \bar{3}, \bar{4}$ are anti-particles of 2, 3, 4, respectively. As in the BBS, 1 represents an empty box whereas $\bar{1}$ plays the role of a particle and anti-particle bound state. The prototype time evolution $T_\infty$ is given by

$$T_\infty = K_2K_3K_4K_5K_6,$$

(2.51)

where each $K_i$ is defined by the following algorithm (we understand $\bar{2} = 2$ etc).

(i) Replace each $\bar{1}$ by a pair $a, \bar{a}$ within a box.

(ii) Move the leftmost $a$ (if any) to the nearest right box which is empty or containing just $\bar{a}$.

(Boxes involving the pair $a, \bar{a}$ are prohibited as the destination.)

(iii) Repeat (ii) until all $a$'s are moved exactly once.

(iv) Replace the pair $a, \bar{a}$ within a box (if any) by $\bar{1}$.

When anti-particles are absent, (i) and (iv) become void and the algorithm reduces to the one for the BBS in proposition 2.6.

Example 2.17. $D_4^{(1)}$-automaton. We write $., a, b, c, d$ for 1, $\bar{1}, \bar{2}, \bar{3}, \bar{4}$, respectively.

$t=0$ \hspace{5mm} $b2\ldots b2\ldots$ \hspace{5mm} $t=2$ \hspace{5mm} $b23\ldots$

$t=1$ \hspace{5mm} $\ldots b22\ldots$ \hspace{5mm} $\ldots a23\ldots$

$t=2$ \hspace{5mm} $\ldots b223\ldots$ \hspace{5mm} $\ldots \ldots a32\ldots$

$t=3$ \hspace{5mm} $\ldots \ldots c32\ldots$ \hspace{5mm} $\ldots \ldots \ldots d24\ldots$

$t=4$ \hspace{5mm} $\ldots \ldots \ldots \ldots c\ldots \ldots$ \hspace{5mm} $\ldots \ldots \ldots a\ldots$

$t=5$ \hspace{5mm} $\ldots \ldots \ldots \ldots \ldots \ldots$ \hspace{5mm} $\ldots \ldots \ldots \ldots 23c3\ldots$

$t=6$ \hspace{5mm} $\ldots \ldots \ldots \ldots \ldots \ldots$ \hspace{5mm} $t=3$ \hspace{5mm} $\ldots \ldots \ldots \ldots \ldots \ldots$

A soliton is a consecutive array of the form $2\bar{3}3\bar{4}4\bar{3}4\bar{4}2\bar{2}2\bar{2}$, where $v_1/v_4 = 0$. Left: successive time evolutions under $T_\infty$, where pair annihilation/creation $b2 \rightarrow c3$ takes place in the scattering. Right: the intermediate states between $t = 2$ and $t = 3$ corresponding to (2.51), where procedures (i)–(iv) can be checked.
In general, it is expected that the so-called Kirillov–Reshetikhin module has the crystal base [61] and one can use its crystal to construct the corresponding generalization of the BBS. • **Supersymmetric case.** The supersymmetric automaton given by the crystal for the super Lie algebra $A(m, n)$ was introduced in [26]. We have fermionic balls labeled by $m + 2, \ldots, m + n + 1$, besides the empty boxes labeled by 1 and the (bosonic) balls labeled by 2, \ldots, $m + 1$. The time evolution rule is the same as that for the $\hat{sl}_{m+1}$-automaton in proposition 2.6, except for the step to move a ball with a fermionic label $a$. For a fermionic label $a$, we replace (iii) of proposition 2.6 with (iii'): exchange the leftmost $a$ among the rest of the $a$s with its nearest right 1 if this $a$ has not been overtaken by the previously moved $a$.

This rule denotes that each soliton can contain at most one fermionic ball of each label.

**Example 2.18.** $A(1, 1)$-automaton. The constraint in (iii') with $a = 3$ is relevant in the steps from $t = 1$ to $t = 2$ and from $t = 2$ to $t = 3$.

\begin{align*}
t=0 & \cdots 322 \cdots 3 \cdots 322 \cdots \cdots \\
t=1 & \cdots 3322 \cdots \cdots \cdots \\
t=2 & \cdots 3 \cdots 322 \cdots \cdots \\
t=3 & \cdots \cdots 322 \cdots \\
t=4 & \cdots \cdots 3 \cdots 322 \cdots \\
\end{align*}

3. **Bethe ansatz approach**

3.1. **Introduction**

The KKR bijection [40, 42] is a one to one correspondence

$$\phi^{-1}: \{\text{rigged configurations}\} \rightleftharpoons \{\text{highest paths}\}. \quad (3.1)$$

It originates in Bethe’s consideration on the completeness of the Bethe ansatz under the string hypothesis [8]. We shall explain (3.1) after a brief exposition on the background along the simplest example from $\hat{sl}_2$.

Consider the spin-$\frac{1}{2}$ Heisenberg chain with the Hamiltonian acting on $(\mathbb{C}^2)^{\otimes L}$,

$$\mathcal{H} = \sum_{k=1}^{L} (\sigma^x_k \sigma^x_{k+1} + \sigma^y_k \sigma^y_{k+1} + \sigma^z_k \sigma^z_{k+1} - 1). \quad (3.2)$$

Here, $\sigma^a_k$ is a Pauli matrix acting on the $k$th site and the periodic boundary condition $\sigma^a_{L+1} = \sigma^a_{1}$ is assumed. The model possesses the (global) $\hat{sl}_2$ symmetry in the sense that $\sigma^a := \sum_k \sigma^a_k$ satisfies the defining relations of $\hat{sl}_2$, and $[\sigma^a, \mathcal{H}] = 0$. Let $\mathbb{C}^2 = \mathbb{C}v_1 \oplus \mathbb{C}v_2$, where $v_1$ and $v_2$ are regarded as spin-up and spin-down local states, respectively. As a consequence of the $\hat{sl}_2$ symmetry, the Hamiltonian $\mathcal{H}$ preserves the number of down (hence up as well) spins, so one may concentrate on a subspace $W_r$ with $r$ down-spins and $L - r$ up-spins. The diagonalization of $\mathcal{H}$ is done by the Bethe ansatz [8]. It reduces the task to finding the solutions of the Bethe equation $(r \leq L/2)$:

$$\left( \frac{u_j + i}{u_j - i} \right)^L = - \prod_{k=1}^{r} \left( \frac{u_j - u_k + 2i}{u_j - u_k - 2i} \right) \quad (j = 1, \ldots, r). \quad (3.3)$$

In term of the Bethe roots $\{u_1, \ldots, u_r\}$, one can construct the eigenvector $|u_1, \ldots, u_r\rangle \in W_r$, called the Bethe vector, of $\mathcal{H}$ whose eigenvalue is given by $\sum_{j=1}^{r} \frac{3}{2u_j^2}$. It is known that the Heisenberg Hamiltonian is contained in the commuting transfer matrices $(T_m(z))_{m \geq 1}$ (2.11) with $q = 1$ as $T_1(z) = T_1(1)(1 + \text{const}(z - 1)\mathcal{H} + \cdots)$ (cf [6, section 10.14]). Thus, the Bethe
equation (3.3) is actually relevant to their joint spectrum and therefore to the ‘diagonalization’ of the commuting time evolutions $T_m$ in the BBS (although the latter corresponds to $q = 0$ rather than $q = 1$).

Back to (3.3), the variety of eigenvalues is provided by the variety of solutions to the Bethe equation. Thus, a basic question arises: how many solutions should there be for the completeness of the Bethe ansatz? The answer is $\binom{L}{r} - \binom{L}{r-1}$.\(^5\) The decrement from $\text{dim } W_r = \binom{L}{r}$ is due to the fact that the Bethe vectors are by construction highest weight vectors annihilated by the $\mathfrak{sl}_2$ raising operator. Namely, it has the property $\sigma^+ |u_1, \ldots, u_r\rangle = 0$ with $\sigma^+ = (\sigma^x + i\sigma^y)/2$ by construction [14, 8]. By virtue of the $\mathfrak{sl}_2$ symmetry, the other eigenvectors can be produced by applying the lowering operator $\sigma^- = (\sigma^x - i\sigma^y)/2$ successively. Thus, one should be content with capturing all the highest weight vectors as Bethe vectors.

Let us observe an example $L = 6, r = 3$. There are certainly $\binom{6}{3} - \binom{6}{2} = 5$ solutions as given below.

\[
\begin{array}{ccc}
0.8585 & -0.8585 \\
0 & 0 \\
0 & 0
\end{array}
\quad
\begin{array}{ccc}
-2.0175i & 2.0175i \\
0 & 0 \\
0 & 0
\end{array}
\]

Here each Bethe root $u_j$ is depicted as $.\quad$ Within each solution, they are grouped into strings. \quad A string is an array of $\bullet$ which is symmetric with respect to the real axis and equidistant of difference $2i$ with possibly ‘negligible’ distortions. Strings consisting of $k$ $\bullet$s are called $k$-strings. \quad In the top-left (right) solution, there are three 1-strings (one 3-string). \quad The three solutions in the bottom line consist of a 1-string and a 2-string with different real parts (called centers). \quad These features are conveniently symbolized in a Young diagram (called configuration) where each row is attached with a nonnegative integer (called rigging) as shown in the figure. \quad They are examples of rigged configurations. \quad Each row including the rigging signifies the length and the center of the string encoded as an integer. \quad They are to obey a certain selection rule that will be specified later in a more general setting. \quad (See (3.12). The way to find the rigging will also be explained in section 3.2.) To summarize so far, rigged configurations are the combinatorial analog of the pattern of Bethe roots under the string hypothesis.

Let us turn to the rhs of (3.1). Bethe vectors have the form $|u_1, \ldots, u_r\rangle = \sum c_{i_1, \ldots, i_L} v_{i_1} \otimes \cdots \otimes v_{i_L} \in W_r$, where the sum runs over $i_1, \ldots, i_L \in \{1, 2\}$ such that $\# \{i_1, \ldots, i_L\} = L - r$ and

\[^5\text{In this argument, independence of the associated Bethe vectors has not been taken into account, and all the Bethe roots are supposed to be finite.}\]
#2[i1,...,iL] = r. Highest paths are their combinatorial analog represented as the sequence
i1, ..., iL ∈ {1, 2}L satisfying the same condition as above and

\[ \#_1[i_1, ..., i_k] \geq \#_2[i_1, ..., i_k] \text{ for } 1 \leq k \leq L. \]  

(3.4)

This is a remnant of the highest condition \( \sigma^+[u_1, ..., u_r] = 0 \). There are \( \binom{L}{j} - \binom{L}{j-1} \) highest paths as expected. In our example \( L = 6, r = 3 \), the highest paths and the corresponding rigged configurations in (3.1) are given as follows:

\[
\begin{array}{c}
\begin{array}{c}
\emptyset \\
0 \\
0
\end{array}
\end{array}
\longleftrightarrow 121212
\]

\[
\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
\emptyset \\
0 \\
0
\end{array}
\end{array}
\end{array}
\longleftrightarrow 112222
\]

(3.5)

This is an example of the KKR bijection. The arrow \( \rightarrow \) here, or equivalently the map \( \phi^{-1} \) in (3.1), is a combinatorial analog of the Bethe ansatz which produces Bethe vectors from Bethe roots as \( \{u_1, ..., u_r\} \mapsto \{\iota_1, ..., \iota_r\} \).

The (vague) claim that any solution of the Bethe equation can be described as a collection of strings is called the string hypothesis. It is known that the string hypothesis is not always valid literally (see, for example, [13]). Nevertheless, as we will illustrate below for the \( \hat{a}_r \) case, one can define rigged configurations and highest paths and establish their bijective correspondence mathematically.

### 3.2. KKR bijection

Let \( B\hat{a}_r \) be the \( \hat{a}_r \) crystal (2.17) with \( l = 1 \). For simplicity, we will exclusively consider the crystal of the form \( B\hat{a}_r^L \) (\( L \in \mathbb{Z}_{\geq 1} \)) and call its elements as paths. For a Young diagram \( \lambda \) with \( |\lambda| = L \) and depth at most \( n + 1 \), elements of the set

\[ \mathcal{P}_+(L, \lambda) = \{ p \in B\hat{a}_r^L \mid \hat{e}_i p = 0 (1 \leq i \leq n), \text{ wt } p = \lambda \} \]  

(3.6)

are called highest paths with weight \( \lambda \). Setting \( p = [i_1] \otimes \cdots \otimes [i_L] \), the highest condition \( \hat{e}_i p = 0 (1 \leq i \leq n) \) is concretely described as

\[ \#_1[i_1, ..., i_k] \geq \#_2[i_1, ..., i_k] \geq \cdots \geq \#_{n+1}[i_1, ..., i_k] \text{ for } 1 \leq k \leq L, \]  

(3.7)

which is a generalization of (3.4). By the condition wt \( p = \lambda \), we mean

\[ \#_a[i_1, ..., i_L] = \lambda_a \quad (1 \leq a \leq n + 1). \]  

(3.8)

Let us proceed to the definition of the rigged configurations. Let \( \mu^{(0)}, \mu^{(1)}, ..., \mu^{(n)} \) be an \( (n + 1) \)-tuple of Young diagrams. We will always take \( \mu^{(0)} = (1^L) (L \in \mathbb{Z}_{\geq 1}) \) which will match the choice of the crystal \( B\hat{a}_r^L \) in (3.6). Denote by \( m_j^{(a)} \) the number of length \( j \) rows in \( \mu^{(a)} \) and introduce the following:

\[ p_j^{(a)} = q_j^{(a-1)} - 2q_j^{(a)} + q_j^{(a+1)} \quad (1 \leq a \leq n), \]  

(3.9)

\[ q_j^{(a)} = \sum_{k \geq 1} \min(j, k)m_k^{(a)} \quad (q_j^{(0+1)} = 0). \]  

(3.10)

By definition \( m_j^{(0)} = \ell \delta_{j,1} \) and \( q_j^{(0)} = L \) for \( j \geq 1 \). In general, \( q_j^{(a)} \) is the number of cells in the left \( j \) columns of \( \mu^{(a)} \). The integer \( p_j^{(a)} \) is called a vacancy and will play an important role in what follows.
An \((n + 1)\)-tuple of Young diagrams \((\mu^{(0)}, \ldots, \mu^{(n)})\) is a configuration if \(p_j^{(a)} \geq 0\) for any \(1 \leq a \leq n\) and \(j \in \mathbb{Z}_{\geq 1}\) such that \(m_j^{(a)} \geq 1\). Such a pair \((a, j)\) (i.e. the \(m_j^{(a)} \times j\) rectangle constituting \(\mu^{(a)}\)) will be referred to as a block.

Given a configuration \((\mu^{(0)}, \ldots, \mu^{(n)})\), we attach a rigging \(J^{(a)}_{j_a} \in \mathbb{Z}_{\geq 0}\) to every row in \(\mu^{(a)}\) except \(\mu^{(0)} = (1^r)\) as follows (shown for a block \((a, j)\)):

\[
\begin{array}{c}
\bullet \downarrow \\
\mu^{(a)}
\end{array}
\begin{array}{c}
m_j^{(a)}
\end{array}
\begin{array}{c}
j
\end{array}
\begin{array}{c}
J^{(a)}_{j,m_j^{(a)}}
\end{array}
\begin{array}{c}
\vdots
\end{array}
\begin{array}{c}
J^{(a)}_{j,1}
\end{array}
\]

(3.11)

We group the rigging as \(J = (J^{(1)}, \ldots, J^{(n)})\) where \(J^{(a)} = (J^{(a)}_{j_a})_{j \geq 1, 1 \leq a \leq m_j^{(a)}}\) is the one attached to \(\mu^{(a)}\). A configuration \(((1^L), \mu^{(1)}, \ldots, \mu^{(n)})\) attached with a rigging \(J = (J^{(1)}, \ldots, J^{(n)})\) will be denoted by \((\mu, J)\), with \(\mu = (\mu^{(1)}, \ldots, \mu^{(n)})\). We say \((\mu, J)\) is a rigged configuration if the condition

\[
0 \leq J^{(a)}_{j,1} \leq J^{(a)}_{j,2} \leq \cdots \leq J^{(a)}_{j,m_j^{(a)}} \leq p_j^{(a)}
\]

is satisfied for all the blocks \((a, j)\).\(^7\)

**Example 3.1.** We list all the rigged configurations having the configuration \(((1^8), (2, 1, 1))\) with \(\mu^{(1)} = (2, 1, 1)\). To save space, only the \((\mu^{(1)}, J^{(1)})\) part is given.

\[
\begin{array}{cccccccc}
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
2 & 0 & 2 & 0 & 2 & 1 & 2 & 0 \\
2 & 1 & 2 & 1 & 2 & 0 & 2 & 2
\end{array}
\]  

(3.13)

For later convenience, we have exhibited the vacancy \(p_2^{(1)} = 0\) and \(p_1^{(1)} = 2\) to the left of the relevant blocks.

**Example 3.2.** An \(n = 3\) example. Again, vacancies, e.g. \(p_2^{(1)} = 5\), are exhibited.

\[
\begin{array}{cccccccc}
\mu^{(0)}_{(1^4)} & \mu^{(1)}_{(2)} & \mu^{(2)}_{(1)} & \mu^{(3)}_{(0)} \\
0 & 0 & 1 & 0 \\
2 & 2 & 0 & 0 \\
2 & 3 & 2 & 0
\end{array}
\]

(3.14)

A weight of a rigged configuration \((\mu, J)\) is the Young diagram \(\lambda = (\lambda_1, \ldots, \lambda_{n+1})\) specified by

\[
|\mu^{(a)}| = \lambda_{a+1} + \lambda_{a+2} + \cdots + \lambda_{n+1} \quad (0 \leq a \leq n).
\]

(3.15)

We write it as \(\text{wt}(\mu, J) = \lambda\), which is actually dependent only on the configuration. The inequality \(\lambda_1 \geq \cdots \geq \lambda_{n+1} \geq 0\) is guaranteed by the condition \(p^{(a)}_{\lambda_{a+1}} = |\mu^{(a-1)}| - 2|\mu^{(a)}| + |\mu^{(a+1)}| \geq 0\) for \(1 \leq a \leq n\). Note also that \(|\lambda| = L\). Let \(\text{RC}(L, \lambda)\) be the set of rigged configurations of weight \(\lambda\).

6. This condition is known actually to ensure that \(p_j^{(a)} \geq 0\) for all \(j \in \mathbb{Z}_{\geq 1}\).

7. Equivalently, one may only impose \(0 \leq J^{(a)}_{j,1}, \ldots, J^{(a)}_{j,m_j^{(a)}} \leq p_j^{(a)}\) and identify their permutations.
Theorem 3.3. For any \( L \in \mathbb{Z}_{\geq 1} \) and a Young diagram \( \lambda \) with \( |\lambda| = L \), there is a bijection

\[
\phi^{-1} : \text{RC}(L, \lambda) \leftrightarrow \mathcal{P}_+(L, \lambda).
\]

(3.16)

The original KKR bijection [40, 42] is the one between rigged configurations and the Littlewood–Richardson tableaux. Its ultimate generalization for type \( \tilde{A}_{n+1} \) is available in [44, 65]. In the simple setting of this review, the Littlewood–Richardson tableaux are in one-to-one correspondence with highest paths via the Robinson–Schensted correspondence [18].

We regard a rigged configuration \((\mu, J)_L\) as a multiset of strings. A string corresponds to a row in (3.11). It is a triple \((a, j, J^{(a)}_j)\) consisting of color \( a \), length \( j \) and rigging \( J^{(a)}_j \). A string is singular if \( J^{(a)}_j = p^{(a)}_j \), namely if the rigging attains the allowed maximum in (3.12). We regard the highest path \( p = \prod i_k \) as a word \( i_1i_2\ldots i_L \in \{1, \ldots, n+1\}^L \).

(The Littlewood–Richardson tableau mentioned in the above is the \( Q \)-symbol [18] of this word.)

For simplicity, we first explain the algorithm for \( \phi^{\pm 1} \) for the \( n = 1 \) case. Even in this case, it may look formidably complicated at first glance. However, it is a very well-designed algorithm, and readers will be impressed and pretty well familiarized with it by working out a few examples. The \( m_j^{(1)} \) and the vacancy \( p^{(1)}_j \) will be denoted by \( m_j \) and \( p_j \).

Thus, definition (3.9) becomes \( p_j = L - 2 \sum_k \min(j, k) m_k \). It is useful to remember it as \( p_j = L - 2 \) (number of cells in the left \( j \) columns in the Young diagram).

Algorithm of \( \phi \) for \( n = 1 \). Given a highest path \( i_1\ldots i_L \), we construct the rigging configuration \( \phi(i_1\ldots i_L) = (\mu, J)_L \) inductively with respect to \( L \). When \( L = 0 \), we understand that \( \phi(\cdot) \) is an empty Young diagram. Suppose that \( \phi(i_1\ldots i_L) = (\mu, J)_L \) has been obtained. We are to construct \( (\mu', J')_{L+1} = \phi(i_1\ldots i_L i_{L+1}) \) from \((\mu, J)_L\) and \( i_{L+1} \in \{1, 2\} \).

Case \( i_{L+1} = 1 \). One has \((\mu', J')_{L+1} = (\mu, J)_{L+1} \), which means that no change should be made in the length and rigging of the strings. (By definition, their vacancies \( p_j \) increase uniformly by 1.)

Case \( i_{L+1} = 2 \). (a) If there is no singular string in \((\mu, J)_L\), just additionally create a length 1 singular string with respect to the new configuration. (Its rigging is therefore \( L+1 - 2 \sum_k \min(1, k)(m_k + \delta_{k,1}) \).) (b) If there exist singular strings, pick the longest one among them and let \( \ell \) be its length. (Any choice is OK when there are more than one such strings.) Then, \((\mu', J')_{L+1} \) is obtained by extending the string to length \( \ell + 1 \) and making it singular with respect to the new configuration. (Its rigging is therefore \( L+1 - 2 \sum_k \min(\ell + 1, k)(m_k + \delta_{k,\ell} + \delta_{k,\ell+1}) \).) In either case of (a) and (b), keep the other strings unchanged.

Algorithm of \( \phi^{-1} \) for \( n = 1 \). Given a rigging configuration \((\mu, J)_L\), we construct a highest path \( i_1\ldots i_L = \phi^{-1}((\mu, J)_L) \) inductively with respect to \( L \). We are to determine \( i_L \in \{1, 2\} \) and variable \( (\mu', J')_{L-1} \) such that \( \phi^{-1}((\mu, J)_L) = \phi^{-1}((\mu', J')_{L-1}) i_L \).

If \((\mu, J)_L\) contains no singular string, then \( i_L = 1 \) and \((\mu', J')_{L-1} = (\mu, J)_{L-1} \). The latter means no change should be made in any string. (By definition, their vacancies \( p_j \) decrease uniformly by 1.) If \((\mu, J)_L\) contains singular strings, then \( i_L = 2 \). Pick the shortest singular string and let \( \ell \) be its length. (Any choice is OK when there are more than one such strings.) Then, \((\mu', J')_{L-1} \) is obtained by shortening the string to length \( \ell - 1 \) and making it singular with respect to the new configuration. (Its rigging is therefore \( L - 1 - 2 \sum_k \min(\ell - 1, k)(m_k + \delta_{k,\ell-1} + \delta_{k,\ell}) \).) The other strings are kept unchanged.
Example 3.4. For the rigged configurations in example 3.1, the algorithm of $\phi^{-1}$ proceeds along the arrows. The algorithm of $\phi$ proceeds backward. To save space, $L$ is given in the first line.

$$\begin{array}{cccccccccc}
8 & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 & \text{Im} \phi^{-1} \\
0 & 2 & 0 & 2 & 0 & 2 & 0 & 1 & 0 & 0 \\
0 & 2 & 0 & 2 & 0 & 1 & 0 & 0 & 2 & 0 \\
0 & 2 & 0 & 2 & 0 & 1 & 0 & 0 & 2 & 0 \\
0 & 2 & 0 & 2 & 0 & 2 & 0 & 1 & 0 & 0 \\
0 & 2 & 0 & 2 & 0 & 2 & 0 & 1 & 0 & 0 
\end{array}$$

Note that one should keep updating the vacancies with $L$.

Now we proceed to the $n$ general case. The basic idea is to apply the removal/addition procedure for the $n = 1$ case recursively in the direction of color.

**Algorithm of $\phi$ for general $n$.** Given a highest path $i_1 \ldots i_d$, we construct the rigged configuration $\phi(i_1 \ldots i_d) = (\mu, J)_L$ inductively with respect to $L$. When $L = 0$, we understand that $\phi(\cdot)$ is the array of empty Young diagrams. Suppose that $\phi(i_1 \ldots i_d) = (\mu, J)_L$ has been obtained. Denote $i_{L+1} \in \{1, \ldots, n+1\}$ simply by $d$. We are to construct $(\mu', J')_{L+1} = \phi(i_1 \ldots i_d)$ from $(\mu, J)_L$ and $d$. If $d = 1$, then $(\mu', J')_{L+1} = (\mu, J)_{L+1}$, which means that no change should be made on any string. (By definition (3.9), the vacancies $p_j^{(\omega)}$ increase by $\delta_{d1}$.) Suppose $d \geq 2$.

(i) Set $\ell(d) = \infty$. For $c = d - 1, d - 2, \ldots, 1$ in this order, proceed as follows. Find the color $c$ singular string whose length $\ell^{(c)}$ is largest within the condition $\ell^{(c)} \leq \ell^{(c+1)}$. If there are more than one such strings, pick any one of them. If there is no such string with color $c$, set $\ell^{(c)} = 0$. Denote these selected strings by $(c, \ell^{(c)}, J^{(c)})$ with $c = d - 1, d - 2, \ldots, 1$, where it is actually void when $\ell^{(c)} = 0$.

(ii) Replace the selected string $(c, \ell^{(c)}, J^{(c)})$ by $(c, \ell^{(c+1)} + 1, J^{(c)})$ for all $c = d - 1, d - 2, \ldots, 1$, leaving the other strings unchanged. Here the new rigging $J^{(c)}$ is to be chosen so that the extended string $(c, \ell^{(c)}, J^{(c)})$ becomes singular with respect to the resulting new rigged configuration $(\mu', J')_{L+1}$.

The algorithm is known to be well defined and the resulting object gives the sought rigged configuration $(\mu', J')_{L+1} = \phi(i_1 \ldots i_d)$.

**Algorithm of $\phi^{-1}$ for general $n$.** Given a rigged configuration $(\mu, J)_L$, we construct a highest path $i_1 \ldots i_d = \phi^{-1}(\mu, J)_L$ inductively with respect to $L$. We are to determine $d = i_L \in \{1, \ldots, n+1\}$ and $(\mu', J')_{L-1}$ such that $\phi^{-1}(\mu, J)_L = \phi^{-1}(\mu', J')_{L-1})d$.

(i) Set $\ell^{(0)} = 1$. For $c = 1, 2, \ldots, n$ in this order, proceed as follows until stopped. Find the color $c$ singular string whose length $\ell^{(c)}$ is smallest within the condition $\ell^{(c)} \geq \ell^{(c+1)}$. Proceed as in step (i) for color $c$.
If there are more than one such strings, pick any one of them. If there is no such string with color \( c \), set \( d = c \) and stop. Denote these selected strings by \( (c, \ell^{(c)}, J^{(c)}) \) with \( c = 1, 2, \ldots, d - 1 \).

(ii) Replace the selected string \( (c, \ell^{(c)}, J^{(c)}) \) by \( (c, \ell^{(c)} - 1, J^{(c)}_{\text{•}}) \) for all \( c = 1, 2, \ldots, d - 1 \) leaving the other strings unchanged. When \( \ell^{(c)} = 1 \), this means that the length 1 string is to be eliminated. The new rigging \( J^{(c)}_{\text{•}} \) is to be chosen so that the shortened string \( (c, \ell^{(c)} - 1, J^{(c)}_{\text{•}}) \) becomes singular in the new data \( (\mu^{\prime}, J^{\prime})_{L-1} \).

For an empty rigged configuration, we understand that \( \phi^{-1}((\emptyset, \emptyset)_L) = \phi^{-1}((\emptyset, \emptyset)_{L-1}) \).

\[ \cdots = 11 \ldots 1. \]

The algorithm is known to be well defined and ends up with the empty rigged configuration at \( L = 0 \). The resulting sequence gives the sought highest path \( i_1 \ldots i_L = \phi^{-1}((\mu, J)_L) \).

**Example 3.5.** The algorithm of \( \phi^{-1} \) for the rigged configurations in example 3.2. For convenience, the vacancy \( p_j^{(a)} \) is shown to the left of each block \( (a, j) \). The rightmost cell in the singular strings to be shorten is indicated by \( \times \).

Thus, the image is the highest path \( 11112221322433 \in B_{L}^{14} \). The algorithm of \( \phi \) proceeds backward.

**Remark 3.6.** Let \( \mathcal{P}(L, \lambda) = \{ p \in B_{L}^{1L} | \text{wt } p = \lambda \} \) be the set of all the weight \( \lambda \) paths including nonhighest paths. It is known that the algorithms for \( \phi \) and \( \phi^{-1} \) actually work in a wider setting so that (3.16) is generalized to \( \phi(\mathcal{P}(L, \lambda)) \equiv \mathcal{P}(L, \lambda) \). The set \( \phi(\mathcal{P}(L, \lambda)) \) of extended rigged configurations is characterized by (3.12) with a non-trivial lower bound [10].

### 3.3 Inverse scattering method

Let \( p = b_1 \otimes \cdots \otimes b_L \in B_{L}^{1L} \) be a state of the BBS satisfying the boundary condition (2.41). Suppose that \( p \) is highest and of weight \( \lambda \), i.e. \( p \in \mathcal{P}_+(L, \lambda) \). Then, the state \( T_l(p) \) after the
time evolution also belongs to \( P_+ (L, \lambda) \). Thus, via the KKR bijection (3.16), \( T_l \) on BBS states induces a time evolution of rigged configurations. The following theorem presents its explicit form.

**Theorem 3.7** [49, proposition 2.6]. For the subset of paths that undergo time evolutions without boundary effects, the commutative diagram

\[
P_+ (L, \lambda) \xrightarrow{\phi} \text{RC}(L, \lambda) \\
\downarrow T_l \quad \downarrow T_l \\
P_+ (L, \lambda) \xrightarrow{\phi} \text{RC}(L, \lambda)
\]

holds with the following time evolution \( T_l \) on rigged configurations:

\[
T_l: (\mu, J)_L \mapsto (\mu, J')_L, \quad J' = (J_1', J_2', \ldots, J_n') = J_1' + \min(I, J).
\]

Namely, the KKR bijection linearizes the dynamics. More concretely, we find that \( (\mu(1), \ldots, \mu(n)), (J_2', \ldots, J_n') \) are conserved (action variable),

\[
J_{1,a}' \text{ changes linearly (angle variables).}
\]

Let us write (3.19) as \( J' = J + h_l \), where \( h_l = (\delta_a \min(l, j))_{a, l, a} \) plays the role of the \( (l) \)th velocity vector. The commutative diagram (3.17) provides a solution of the initial value problem in the BBS. For a state \( p \), it is given as \( T_N^l(p) = \phi^{-1} \circ T_l^N \circ \phi(p) \), where the \( T_l^N \) on the rhs is just to change the rigging as \( J \mapsto J + Nh_l \). The variety of time evolutions \( T_1, T_2, \ldots \) is reflected in the velocity vectors \( h_1, h_2, \ldots \).

**Example 3.8.** The time evolution of the rigged configurations under \( T_{\infty} \) corresponding to example 2.11:

\[
\begin{array}{c|c|c|c|}
\mu^{(0)}_l (158) & \mu^{(1)}_l & \mu^{(2)}_l & \mu^{(3)}_l \\
\hline
4 + 4t & 10 + 3t & 1 & 0 \\
15 + 2t & & & \\
\end{array}
\]

In example 3.8, one notices that \( \mu^{(1)} = (4, 3, 2) \) gives the list of amplitudes of solitons. This fact holds in general, which is a manifestation of the Bethe ansatz structure in the BBS:

\[
\mu^{(1)} = \text{list of amplitudes of solitons.}
\]

We call it *soliton/string correspondence*. In fact, \( \mu^{(1)} \) is related to the earlier introduced conserved quantity \( E_l \) (2.44) as

\[
E_l = \text{number of cells in the left } l \text{ columns of } \mu^{(1)}.
\]

There are still more conserved quantities in (3.20) than \( \mu^{(1)} \). They are responsible for the *internal labels* of colliding solitons\(^8\).

---

\(^8\) The data (3.20) is regarded as a rigged configuration for \( \hat{a}_k \) (instead of \( \hat{a}_{k+1} \)) and the solitons are determined as its image under the KKR map \( \phi^{-1} \). See [49, 53] for details.
The inverse scattering scheme explained so far is naturally extended to not necessarily highest states by remark 3.6 as long as the boundary effect is absent. For \( n = 1 \), the solution of the initial value problem in the same spirit has also been obtained in [66]. It was an essential insight of the quantum inverse scattering method [64] that the Bethe ansatz can be viewed as a quantization of the classical inverse scattering method [1, 19]. It is gratifying to realize that the combinatorial version of the Bethe ansatz here provides the inverse scattering scheme of the BBS which is a crystalline quantum integrable system. In this respect, the KKR maps \( \phi \) and \( \phi^{-1} \) are the direct and inverse scattering transforms and the rigged configurations play the role of scattering data [49].

4. Ultradiscretization—min–plus algebra

4.1. Tropicalization and ultradiscretization

Define \( \mathbb{T} = \mathbb{R} \cup \{\infty\} \) where \( \infty \) is the infinity which satisfies \( a < \infty \) and \( \infty + a = \infty \) for any \( a \in \mathbb{R} \). The algebra \( (\mathbb{T}, \oplus, \odot) \) is called the min–plus algebra (or the tropical semifield) [62], where the two operations ‘\( \oplus \)’ and ‘\( \odot \)’ in \( \mathbb{T} \) are respectively called tropical addition and tropical multiplication defined by

\[
\begin{align*}
\quad a \oplus b & := \min(a, b), & \quad a \odot b & := a + b.
\end{align*}
\]

The additive identity is \( \infty \) and the multiplicative identity is 0, i.e.

\[
\begin{align*}
\quad a \oplus \infty & = a, & \quad a \odot 0 & = a
\end{align*}
\]

hold for any \( a \in \mathbb{T} \). We have the inverse of \( \odot \) as \( a \odot (-a) = 0 \), but not the inverse of \( \oplus \). In the following, we also write \((\mathbb{T}, \min, +)\) for \((\mathbb{T}, \oplus, \odot)\).

We are to introduce a limiting procedure called the tropicalization, which links the subtraction-free algebra \((\mathbb{R}_{>0}, +, \times)\) to the min–plus algebra. We define a map \( \text{Log}_\varepsilon : \mathbb{R}_{>0} \rightarrow \mathbb{R} \) with an infinitesimal parameter \( \varepsilon > 0 \) by

\[
\text{Log}_\varepsilon : a \mapsto -\varepsilon \log a.
\]

(4.1)

For \( a > 0 \), define \( A \in \mathbb{R} \) by \( a = e^{-\frac{1}{\varepsilon}} \). Then, we have \( \text{Log}_\varepsilon (a) = A \). Moreover, for \( a, b > 0 \) define \( A, B \in \mathbb{R} \) by \( a = e^{-\frac{1}{\varepsilon}} \) and \( b = e^{-\frac{1}{\varepsilon}} \). Then, we have

\[
\begin{align*}
\text{Log}_\varepsilon (a + b) & = -\varepsilon \log(e^{-\frac{1}{\varepsilon}} + e^{-\frac{1}{\varepsilon}}), & \text{Log}_\varepsilon (a \times b) & = A + B.
\end{align*}
\]

In the limit \( \varepsilon \rightarrow 0 \), \( \text{Log}_\varepsilon (a + b) \) becomes \( \min(A, B) \). In this manner, the algebra \((\mathbb{R}_{>0}, +, \times)\) reduces to the min–plus algebra, and the procedure \( \lim_{\varepsilon \rightarrow 0} \text{Log}_\varepsilon \) with the transformation as \( a = e^{-\frac{1}{\varepsilon}} \) is called the tropicalization.

Through the tropicalization, subtraction-free rational equations on \( \mathbb{R}_{>0} \) reduce to piecewise-linear equations on \( \mathbb{R} \) described by min–plus algebra, which is summarized as follows: for \( A, B, C \in \mathbb{R} \) set

\[
\begin{align*}
\quad a = e^{-\frac{1}{\varepsilon}}, & \quad b = e^{-\frac{1}{\varepsilon}}, & \quad c = e^{-\frac{1}{\varepsilon}}
\end{align*}
\]

and take the limit \( \varepsilon \rightarrow 0 \) of the image \( \text{Log}_\varepsilon \) of the equations

\[
\begin{align*}
(i) & \quad a + b = c, & \quad (ii) & \quad ab = c, & \quad (iii) & \quad \frac{a}{b} = c.
\end{align*}
\]

Then, we obtain

\[
\begin{align*}
(i) & \quad \min(A, B) = C, & \quad (ii) & \quad A + B = C, & \quad (iii) & \quad A - B = C.
\end{align*}
\]

We remark that the distributive law of the algebra \((\mathbb{R}_{>0}, +, \times)\), \( a(b + c) = ab + ac \), reduces to that of the min–plus algebra, \( A + \min(B, C) = \min(A + B, A + C) \).

Let us show an example.
**Example 4.1.** The discrete Lotka–Volterra equation for the variables \( v^m_j \) \((j, m) \in \mathbb{Z}^2\) is given by

\[
\frac{v^m_{j+1}}{v^m_j} = \frac{1 + \delta v^m_{j-1}}{1 + \delta v^{m+1}_{j+1}},
\]

where \(\delta\) is a positive parameter. We restrict \( v^m_j \in \mathbb{R}, \delta > 0\) and take transformations \(\delta = e^{-\frac{1}{\tau}}\) and \(v^m_j = e^{-\frac{v_j}{\tau}}\). Then, the tropicalization of (4.2) is calculated as

\[
V^{m+1}_j - V^m_j = -\lim_{\varepsilon \to 0} \varepsilon \left( \log \left(1 + e^{-1+m^{m+1}_j}\right) - \log \left(1 + e^{-1+m^m_j}\right) \right)
= \min \left(0, V^{m-1}_j + 1\right) - \min \left(0, V^{m+1}_j + 1\right).
\]

By construction, the tropicalization of a discrete equation is defined on \(\mathbb{R}\), i.e. the dependent variables of the tropicalization are in \(\mathbb{R}\). When the tropicalization is defined on \(\mathbb{Z}\), we call it the ultradiscretization of the discrete equation. In the above example, (4.3) allows for the ultradiscretization, since \(V^{m+1}_j\) is determined as an integer if \(V^m_j, V^{m-1}_j\) and \(V^{m+1}_j\) are integers.

**Remark 4.2.** The original Lotka–Volterra equation \( v_j = v_j(v_{j+1} - v_{j-1}) \) is the continuous limit \(\delta \to 0\) of (4.2) with \(v^m_j = v_j(-\delta m)\). Here, \(\delta\) is a unit of the discrete time and \(v_j\) is a derivation of \(v_j = v_j(t)\) by the time \(t\).

### 4.2. Evolution equations of the BBS

The original BBS in section 1.1 corresponds to the time evolution \(T_{2\infty}\) in the formalism of section 2.3, which is the only case that admits the algorithms (albeit non-local) without a carrier. One can set up two kinds of evolution equations for it:

(i) the equation for the number \(u'_k\) of balls in the \(k\)th box at time \(t\) [77] (the spatial description),

(ii) the equation for the number \(Q_j\) of balls in the \(j\)th soliton (from the left) and the number \(W_j\) of empty boxes between the \(j\)th and the \((j+1)\)th solitons at time \(t\) [75] (the soliton description).

These descriptions are respectively related to the ultradiscretization of famous integrable difference equations, the discrete Lotka–Volterra equation (section 4.2.1) and the discrete Toda lattice equation (section 4.2.2).

#### 4.2.1. Lotka–Volterra equation and infinite BBS

Let \(u'_k \in \{0, 1\}\) be the number of balls in the \(k\)th box at time \(t\). The evolution equation for \(u'_k\) is described by a piecewise-linear equation [77]

\[
u^{i+1}_k = \min \left( 1 - u'_k, \sum_{j=-\infty}^{k-1} (u'_j - u'_j + 1) \right).
\]

This equation has a piecewise-linear version of the bilinear form in the following sense: assume that the variables \(\rho^i_k, \rho^i_{k-1}, k \in \mathbb{Z}\) satisfy

\[
\rho^i_{k+1} + \rho^i_{k-1} = \max (\rho^i_{k+1} + \rho^0_k, \rho^i_{k+1} - \rho^i_{k-1} + 1).
\]

This, the variables \(u'_k, u'_k, k \in \mathbb{Z}\) defined by

\[
u'_k = \rho^i_k + \rho^i_{k+1} - \rho^i_{k-1} - \rho^0_k
\]

satisfy (4.4).
On the other hand, the discrete Lotka–Volterra equation (4.2) has a bilinear form:

\[(1 + \delta) t_{j+1}^m t_j^{m+1} = \delta t_{j+2}^m t_{j-1}^m + t_{j+1}^{m+1} t_j^m, \tag{4.7}\]
i.e. if the variables \(\{v_j^m, j, m \in \mathbb{Z}\}\) satisfy the bilinear difference equation (4.7), then the variables \(\{v_j^m, j, m \in \mathbb{Z}\}\) defined by

\[v_j^m = \frac{t_{j+1}^m t_j^{m+1}}{t_{j+2}^m t_{j-1}^m} \tag{4.8}\]
satisfy (4.2).

**Proposition 4.3** [77]. Equation (4.5) is the ultradiscretization of the bilinear form (4.7) with the transformations \(\delta = e^{-1}\) and \(\sigma_1^k = e^{\frac{k}{t}}\) under a coordinate transformation \(\sigma_1^k := v_{k-1}^1\).

**Proof.** It is obvious that (4.5) can be defined on \(\mathbb{Z}\). Via the coordinate transformation, (4.7) becomes

\[(1 + \delta) \sigma_1^{k-1} \sigma_1^{k+1} = \delta \sigma_1^{k+1} \sigma_1^{k+1} + \sigma_1^k \sigma_1^{k+1}. \tag{4.9}\]

By applying the tropicalization with the transformation, we have

\[-\lim_{\varepsilon \to 0} \varepsilon \log (1 + e^{-\varepsilon}) - \rho_k^{j+1} - \rho_k^{j+1} = \lim_{\varepsilon \to 0} \varepsilon \log \left(\frac{e^\varepsilon - 1}{\varepsilon} + \frac{e^\varepsilon - 1}{\varepsilon}\right), \]

which yields (4.5). Here we use

\[\lim_{\varepsilon \to 0} \varepsilon \log (1 + e^{-\varepsilon}) = 0, \lim_{\varepsilon \to 0} \varepsilon \log (e^\varepsilon + e^\varepsilon) = \max(A, B). \]

\[\square\]

**Remark 4.4.** At (4.4), we can regard \(v_{k-1}^1 := \sum_{j \in \mathbb{Z}} (u_j^1 - u_j^{k+1})\) as ‘the number of balls in the carrier’, which is identified with \(v_{k-1}^1\) at (2.39). Then, (4.4) is rewritten as

\[u_k^{j+1} = \min(1 - u_k^j, v_{k-1}^1). \tag{4.10}\]

One sees that these correspond to the description of the BBS with the combinatorial \(R\) of the \(\widehat{sl}_2\) crystal in section 2.2. In fact, for \(n = 1, (2.31)\) simply reads

\[\hat{x}_j - x_j = \min(x_j, y_j) = \min(x_j, y_j+1). \tag{4.11}\]

Thus, by setting \(y = (1 - u_k^j, v_{k-1}^1), \tilde{y} = (1 - \hat{u}_k^j, u_k^{j+1}) \in B_1\) and \(x = (\theta - v_{k-1}^1, v_{k-1}^1), \tilde{x} = (\theta - v_{k-1}^1, v_{k-1}^1) \in B_1, (2.31)\) reduces to (4.10) in the limit \(\theta \to \infty\).

The \(\widehat{sl}_{n+1}\) BBS also has the bilinear form as (4.5). Given a state at time \(t = 0\) as \(p = \cdots \otimes x_k^0 \otimes x_{k+1}^0 \otimes \cdots\) with \(x_k^0 \in B_1\), we consider its time evolution \(T_{\infty}(p) = \cdots \otimes x_k^1 \otimes x_{k+1}^1 \otimes \cdots\) for \(t \geq \tau\). Here, \(x_k^t \in B_1\) specifies the local state of the \(k\)th box at time \(t\). According to (2.17), we express it as \(x_k^t = (x_{k,1}^t, \ldots, x_{k,n+1}^t)\). Define \(\rho_{i,j}^k \in \mathbb{Z}\) \((k \in \mathbb{Z}, i = 0, 1, \ldots, n+1, t \in \mathbb{Z}_{\geq 0}\) by

\[\rho_{i,j}^k = \sum_{j=-\infty}^{\infty} (x_{j,2}^i + x_{j,3}^i + \cdots + x_{j,n+1}^i) + \sum_{j=0}^{\infty} \sum_{j=-\infty}^{\infty} (x_{j,2}^i + x_{j,3}^i + \cdots + x_{j,n+1}^i) \tag{4.12}\]

\[\rho_{i,0}^k = \rho_{i,n+1}^k - k. \]

This counts the number of balls in the SW quadrant of the time evolution profile as in example 2.11. The variables \((k, t)\) specify the position of the top-right corner of the quadrant.
The first term in (4.12) means that only those balls with color \( \leq i \) are counted on the top row of the quadrant. The quantities \( \rho^t_{k,i} \) are finite due to the boundary condition and the BBS time evolution rule. To see this concretely, note that each state at time \( t \) has a finite number of balls; therefore, we have \( x^t_{j,i} = 0 (j < k_0, i = 2, \ldots, n + 1) \) for some \( k_0 \leq k \). Then, the time evolution rule (proposition 2.6) implies that the nonzero contribution to the double infinite sum in (4.12) actually comes from the finite region depicted as

\[
\begin{array}{ccccccc}
x^t_{k_0} & x^t_{k_0+1} & \cdots & x^t_{k-1} & x^t_k \\
x^t_{k_0+1} & x^t_{k_0+2} & \cdots & \cdots & \cdots & \cdots & x^t_{k+1} \\
\vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots \\
x^t_{k+k_0} & \cdots & x^t_{k+2} & \cdots & \cdots & \cdots & \cdots \\
\end{array}
\]

(4.13)

By definition, we have \( \rho^t_{k,n+1} = \rho^t_{k,1} \) and

\[
x^t_{k,i} = \rho^t_{k,i} - \rho^t_{k-1,i} + \rho^t_{k-1,i-1} \quad i = 1, \ldots, n + 1. \tag{4.14}
\]

**Proposition 4.5** [53, proposition 4.2]. The following relation holds:

\[
\rho^t_{k,i+1} + \rho^t_{k-1,i} = \max \left( \rho^t_{k,i}, \rho^t_{k-1,i-1}, \rho^t_{k-1,i+1}, \rho^t_{k,i} + 1 \right) \quad i = 2, \ldots, n + 1. \tag{4.15}
\]

We note that a similar fact is studied in [21, IV]. When \( n = 1 \), we recover (4.5) and (4.6) via \( \rho^t_k = \rho^t_{k,2}, u^t_k = x^t_{k,2} \). The variables \( \rho^t_{k,i} \) will play an important role to solve the BBS in section 4.4.

### 4.2.2. Toda lattice and infinite BBS

Consider a state of the \( \hat{sl}_2 \) BBS with \( N \) solitons, and let \( Q^t_j \) be the number of balls in the \( j \)th soliton and \( W^t_j \) be the number of empty boxes between the \( j \)th soliton and the \((j + 1)\)st soliton at time \( t \) as follows:

\[
\begin{array}{ccccccc}
Q^t_1 & W^t_1 & Q^t_2 & W^t_2 & Q^t_3 & \cdots & Q^t_N \\
\cdots & 1111111 & \cdots & \cdots & \cdots & \cdots & \cdots \\
\end{array}
\]

We have positive integers \( Q^t_j \) for \( j = 1, \ldots, N \) and \( W^t_j \) for \( j = 1, \ldots, N - 1 \) and have \( W^t_N = W^t_{N+1} = \infty \).

The evolution equations for \( Q^t_j \) and \( W^t_j \) are written as [75]

\[
Q^t_{j+1} = \min \left( \sum_{k=1}^{j} Q^t_k - \sum_{k=1}^{j-1} Q^t_{k+1}, W^t_{j} \right) \quad j = 1, \ldots, N, \tag{4.16}
\]

\[
W^t_{j+1} = Q^t_{j+1} + W^t_{j} - Q^t_{j+1} \quad j = 1, \ldots, N - 1. \tag{4.17}
\]

**Example 4.6.** Let us consider the case of \( N = 3 \). In the following, the evolution of a 3-soliton state on the left is written in terms of \( \{Q^t_1, W^t_1, Q^t_2, W^t_2, Q^t_3\} \) on the right:

\[
\begin{array}{ccccccc}
t=0 & 0 & \cdots & \cdots & \cdots & \cdots & \cdots \\
t=1 & 0 & \cdots & \cdots & \cdots & \cdots & \cdots \\
t=2 & 0 & \cdots & \cdots & \cdots & \cdots & \cdots \\
t=3 & 0 & \cdots & \cdots & \cdots & \cdots & \cdots \\
t=4 & 0 & \cdots & \cdots & \cdots & \cdots & \cdots \\
t=5 & 0 & \cdots & \cdots & \cdots & \cdots & \cdots \\
\end{array}
\]

One sees that the variables \( \{Q^t_1, W^t_1, Q^t_2, W^t_2, Q^t_3\} \) satisfy (4.16) and (4.17).
On the other hand, the discrete Toda lattice equation is given by

\[ q_j^{t+1} = q_j^t + W_j^t - W_{j+1}^{t+1} \]  

(4.18)

\[ W_j^{t+1} = \frac{q_j^{t+1} w_j^t}{q_{j-1}^{t+1}} \]  

(4.19)

for \( j, t \in \mathbb{Z} \). Now we only consider (4.18) for \( j = 1, \ldots, N \) and (4.19) for \( j = 1, \ldots, N - 1 \) with the boundary condition \( W_0^t = w_N^t = 0 \). This is what is called the discrete Toda molecule equation.

**Proposition 4.7** [75, section 3]. Equations (4.16) and (4.17) are the ultradiscretization of the discrete Toda molecule equation with \( q_j^t = e^\sigma_j^t \) and \( w_j^t = e^\tau_j^t \).

**Proof.** By using (4.19) iteratively, (4.18) becomes subtraction-free:

\[ q_j^{t+1} = \prod_{k=1}^{j} q_k^t \cdot \prod_{k=j+1}^{N} q_k^{t+1} + w_j^t. \]  

(4.20)

We apply the tropicalization and obtain the claim. Note that the boundary condition for \( W_0^t \) and \( W_N^t \) is consistent with that for \( W_0^t \) and \( W_N^t \). It is clear that (4.16) and (4.17) are defined on \( \mathbb{Z} \). □

**Remark 4.8.** The original Toda lattice equation \( \hat{x}_j = e^\sigma_j - e^\sigma_j^\delta \) is the continuous limit \( \delta \to 0 \) of (4.18) and (4.19) with \( \sigma_j = \delta^2 e^{\sigma_j} \) and \( \sigma_j = 1 + \delta \sigma_j \) in the same manner as the Lotka–Volterra equation at remark 4.2.

**Remark 4.9.** The description (4.16), (4.17) can be generalized to the infinite BBS of type \( \hat{s}_{n+1} \) [75, section 3]. Again we consider a state with \( N \) solitons, where we regard a non-increasing sequence of 2, 3, \( \ldots, n + 1 \) as a soliton (section 2.3.2). Let \( Q_{j,i}^t \) be the number of \( i \)-balls in the \( j \)th soliton and \( W_j^t \) be the number of empty boxes between the \( j \)th soliton and the \( (j + 1) \)th soliton at time \( t \). Then, we have non-negative integers \( Q_{j,i}^t \) \((j = 1, \ldots, N, i = 2, \ldots, n + 1)\) and \( W_j^t \) \((j = 0, \ldots, N)\) satisfying \( \sum_{i=2}^{n+1} Q_{j,i}^t \geq 0 \) and \( W_0^t = W_N^t = \infty \). The other \( W_j^t \) can be zero only if the color of the rightmost ball in the \( j \)th soliton is strictly smaller than that of the leftmost ball in the \( (j + 1) \)th soliton.

We define \( W_j^t \) for \( t \in \mathbb{Z}/n \) and regard \( W_j^t \) with \( t \not\in \mathbb{Z} \) as the intermediate states. The evolution equations are written as

\[ Q_{j,i+1}^{t+1} = \min \left( \sum_{k=1}^{j} Q_{k,i}^t - \sum_{k=1}^{j-1} Q_{k,i+1}^{t+1}, W_j^{t+1 + \frac{i-j}{n}} \right), \quad j = 1, \ldots, N, \]  

(4.21)

\[ W_j^{t+1 + \frac{i-j}{n}} = Q_{j+1,i}^{t+1} + W_j^{t+1 + \frac{i-j}{n}} - Q_{j,i}^{t+1}, \quad j = 1, \ldots, N - 1, \]  

(4.22)

where we run these equations from \( i = n + 1 \) to \( i = 2 \). These piecewise-linear equations correspond to the ultradiscretization of the generalized (or hungry) Toda molecule equation.

**Remark 4.10.** In this description, only the information of relative coordinates of solitons survive, and the information of the absolute coordinates are lost. However, it is sufficient to study the basic features of the BBS such as the soliton scattering and the conserved quantities. See [75] for details.
4.3. Birational $R$ and geometric crystal

The purpose of this subsection is to introduce birational $R$ and geometric crystal for $\widehat{sl}_{n+1}$ [48, 51]. Besides their conceptual importance, they are useful to describe local evolution rules of discrete integrable systems related to the BBS. They consist of birational maps and many other relations between certain sets of variables. The combinatorial $R$ and the crystal for $\widehat{sl}_{n+1}$ in section 2.2 are obtained from them by ultradiscretization.

4.3.1. Birational $R$. Let $B = \{x = (x_1, \ldots, x_{n+1})\} \subset (\mathbb{C}^*)^{n+1}$ be a set of variables. The birational $R$ (introduced under the name of tropical $R$ in [48, 51]) for $\widehat{sl}_{n+1}$ is the birational map $R : B \times B \to B \times B$ specified by $R(x, y) = (\tilde{y}, \tilde{x})$ in which

$$\tilde{x}_i = x_i \frac{P_{i-1}(x, y)}{P_i(x, y)}, \quad \tilde{y}_i = y_i \frac{P_i(x, y)}{P_{i-1}(x, y)},$$

where all the indices are considered to be in $\mathbb{Z}_{n+1}$. It satisfies the inversion relation $R^2 = id$ on $B \times B$ and the Yang–Baxter equation

$$R_i R_j R_k = R_j R_k R_i,$$

on $B \times B \times B$, where $R_1(x, y, z) = (R(x, y), z)$ and $R_2(x, y, z) = (x, R(y, z))$. A proof will be given later (proposition 4.18).

The birational $R$ is characterized as the unique solution to a version of the discrete Toda lattice equation.

**Proposition 4.11** [79, theorem 2.2]. Given $(x, y)$, the birational $R$ is the unique solution to the equations on $(\tilde{y}, \tilde{x})$:

$$x_i y_i = \tilde{y}_i \tilde{x}_i, \quad \frac{x_i}{x_j} + \frac{1}{y_{i+1}} = \frac{y_i}{y_j} + \frac{1}{\tilde{x}_{i+1}},$$

with an extra constraint $\prod_{i=1}^{n+1} (x_i/\tilde{x}_i) = \prod_{i=1}^{n+1} (y_i/\tilde{y}_i) = 1$.

**Proof.** We prove that the $(\tilde{y}, \tilde{x})$ given by (4.23) satisfies (4.25). The uniqueness of the solution will be discussed later (proposition 4.16). The former equation is clearly satisfied by (4.23). Let us check the latter one. It is equivalent to $P_{i+1}(x, y)/x_{i+1} + P_{i-1}(x, y)/y_i = P_i(x, y)/x_i + P_i(x, y)/y_{i+1}$ which is verified as

$$P_{i+1}(x, y)/x_{i+1} - P_i(x, y)/x_i = \sum_{k=1}^{n} \left( \prod_{j=k}^{n} x_{i+j} \prod_{j=1}^{k} y_{i+j+1} - \prod_{j=k}^{n} x_{i+j} \prod_{j=1}^{k} y_{i+j} \right) = \sum_{k=2}^{n+1} \left( \prod_{j=k}^{n+1} x_{i+j} \prod_{j=1}^{k} y_{i+j} - \prod_{j=k}^{n+1} x_{i+j-1} \prod_{j=1}^{k} y_{i+j-1} \right) = P_i(x, y)/y_{i+1} - P_{i-1}(x, y)/y_i.$$

In order to relate the birational $R$ to the combinatorial $R$, we introduce the max-plus version of the tropicalization. It is a slight modification of the tropicalization in section 4.1.
For $a > 0$, define $A \in \mathbb{R}$ by $a = e^\gamma$. Then, we have $-\log_\epsilon(a) = A$. Moreover, for $a, b > 0$ define $A, B \in \mathbb{R}$ by $a = e^\gamma$ and $b = e^\delta$. Then, we have

$$-\log_\epsilon(a + b) = \epsilon \log(e^\gamma + e^\delta), \quad -\log_\epsilon(a \times b) = A + B.$$ 

In the limit $\epsilon \to 0$, $-\log_\epsilon(a+b)$ becomes $\max(A, B)$. In this manner, the algebra $(\mathbb{R}, +, \times)$ reduces to the ‘max-plus’ algebra, and the procedure $-\lim_{\epsilon \to 0} \log_\epsilon$ with the transformation $a = e^\gamma$ is also called the tropicalization. As in section 4.1, it is called ultradiscretization when defined on $\mathbb{Z}$. We note that this version of the ultradiscretization of (4.23) is (2.31), and that of (4.25) is (2.32), when we take $\mathcal{B} = \{x = (x_1, \ldots, x_{n+1}) | x_i \in \mathbb{R}_{>0} \text{ for all } i\}$.

4.3.2. Geometric crystal. A representation theoretical background for the birational $R$ is provided by the geometric crystals [7] and their natural extrapolation into the affine setting [48, section 1]. We explain this notion for $\tilde{a}_{i,n+1}$.

To give an overview of the basic idea, first we show a few relations in the case of up to twofold tensor products. Let us begin with the crystal. As a result of (2.20)–(2.25) and by interpreting $\tilde{f} = \tilde{c}_i^{-1}$, the action of the Kashiwara operator $\tilde{c}_i$ with a parameter $c \in \mathbb{Z}$ is given, unless they vanish, by

$$\tilde{c}_i^j(x) = (\ldots, x_{i-1}, x_i + c, x_{i+1} = c, x_{i+2}, \ldots), \quad (4.26)$$

$$\tilde{c}_i(x \otimes y) = \tilde{c}_i^1(x) \otimes \tilde{c}_i^1(y),$$

$$c_1 = \max(x_i + c, y_{i+1}) - \max(x_i, y_{i+1}), \quad (4.27)$$

$$c_2 = \max(x_i, y_{i+1}) - \max(x_i, y_{i+1} - c).$$

In the geometric crystal, one still has the coordinates $x = (x_1, \ldots, x_{n+1}) \in \mathcal{B}$ and the corresponding structure looks as $(c \in \mathbb{C}^n)$

$$e_i^j(x) = (\ldots, x_{i-1}, cx_i, c^{-1}x_{i+1}, x_{i+2}, \ldots), \quad (4.28)$$

$$e_i(x, y) = (e_i^1(x), e_i^1(y)), \quad (4.29)$$

$$c_1 = \frac{cx_i + y_{i+1}}{x_i + y_{i+1}}, \quad c_2 = \frac{x_i + y_{i+1}}{x_i + c^{-1}y_{i+1}}.$$ We call $e_i^j$ the geometric Kashiwara operator. Note that the $c_1$, $c_2$ in (4.27) are piecewise-linear and obtained from (4.29) by the ultradiscretization, i.e. replacing $+, \times, /$ with max, $+, -, -$ respectively.

Now we define the geometric crystal for $\tilde{a}_{i,n+1}$ in a more general setting. In what follows, let $c \in \mathbb{C}^n$ be a parameter which takes generic values, $e_i^j$ be a rational transformation on a variable set $\mathcal{V} \subset (\mathbb{C}^n)^N$ where $N \in \mathbb{Z}_{>0}$, and $\epsilon_i, \gamma_i$ are rational functions on $\mathcal{V}$.

**Definition 4.12.** A geometric crystal for $\tilde{a}_{i,n+1}$ is a family $\{\mathcal{V}, \epsilon_i, \gamma_i, e_i^j\}$ which satisfies the following relations. For any $x \in \mathcal{V}, c, c' \in \mathbb{C}^n$ and $i, j \in I = \{0, 1, \ldots, n\}$,

(i) $e_i^je_i^c(x) = e_i^{c'}(x)$, \quad $e_i^1(x) = x$,

(ii) $\epsilon_i(e_i^j(x)) = c^{-1}\epsilon_i(x)$,

(iii) $\gamma_i(e_i^j(x)) = c^2\gamma_i(x)$ if $i = j$, \quad $c^{-1}\gamma_i(x)$ if $i - j \equiv \pm 1$,

(iv) $e_i^j e_i^j(x) = e_i^j e_i^j(x)$ if $i - j \not\equiv \pm 1$,

(v) $e_i^j e_i^j e_i^j(x) = e_i^j e_i^j e_i^j(x)$ if $i - j \equiv \pm 1$.

Here, $i \equiv j$ means $i - j \in (n+1)\mathbb{Z}$.

In what follows, we introduce the function $\psi_i$ by $\gamma_i = \psi_i/\epsilon_i$.

**Example 4.13.** For $x \in \mathcal{V} = \mathcal{B}$, define $e_i^1$ by (4.28) and let $\epsilon_i(x) = x_{i+1}, \psi_i(x) = x_i$. 

36
Example 4.14. For \((x, y) \in \mathcal{V} = \mathcal{B} \times \mathcal{B}\), define \(e_i^r\) by (4.29) and let \(\varepsilon_i(x, y) = x_{i+1}(1 + y_{i+1}/x_i), \varphi_i(x, y) = y_i(1 + x_i/y_{i+1})\).

Example 4.15. For \(x = (x^{(1)}, \ldots, x^{(L)}) \in \mathcal{V} = \mathcal{B}^L\), define \(\varepsilon_i, \varphi_i, e_i^r\) by
\[
\varepsilon_i(x) = \sum_{k=1}^{L} \left( \prod_{j=1}^{k} \varepsilon_i(x^{(j)}) \right) \left( \prod_{j=k+1}^{L-1} \varphi_i(x^{(j)}) \right),
\]
(4.30)
\[
\varphi_i(x) = \sum_{k=1}^{L} \left( \prod_{j=2}^{k} \varepsilon_i(x^{(j)}) \right) \left( \prod_{j=k+1}^{L} \varphi_i(x^{(j)}) \right),
\]
(4.31)
\[
e_i^r(x) = (e_i^{r_1}(x^{(1)}), \ldots, e_i^{r_L}(x^{(L)})),
\]
with \(e_i = \sum_{k=1}^{L} e^{i(k \in I)} \left( \prod_{j=2}^{k} \varepsilon_i(x^{(j)}) \right) \left( \prod_{j=k+1}^{L} \varphi_i(x^{(j)}) \right).
\]
(4.32)
Here, \(\theta(s) = 1\) if \(s\) is true and \(= 0\) otherwise. The \(\varepsilon_i, \varphi_i\) on the right-hand sides are those defined in example 4.13.

When \(c, c' \in \mathbb{R}_{>0}\), all the above relations in the geometric crystal for \(\widehat{\mathfrak{sl}}_{n+1}\) reduces to the corresponding relations in the crystal for \(\mathfrak{sl}_{n+1}\) in section 2.2.1, via the max-plus version of the ultradiscretization.

4.3.3. Matrix realization. There is a matrix realization of the geometric crystal for \(\widehat{\mathfrak{sl}}_{n+1}\), where each element \(x \in \mathcal{B}\) is associated with the matrix
\[
M(x, \zeta) = \begin{pmatrix}
x_{1}^{-1} & -1 & -\zeta^{-1} \\
-1 & x_{2}^{-1} & \ddots \\
\vdots & \ddots & \ddots & -1 \\
-\zeta^{-1} & \ddots & \ddots & \ddots & -1 \\
& \ddots & \ddots & \ddots & \ddots \\
& & \ddots & \ddots & \ddots \\
\end{pmatrix}^{-1}
\]
(4.33)
involving the spectral parameter \(\zeta\). The structure of the \(\widehat{\mathfrak{sl}}_{n+1}\) geometric crystal is realized as simple matrix operations. The action of the geometric Kashiwara operator is induced by a multiplication of (product of) \(M\) with certain unipotent matrices. For simplicity, we assume \(i \neq 0\) in what follows. Let \(G_{i}(a) = E + aE_{i+1}\) where \(E\) is the identity matrix. Then, we have
\[
G_{i} \left( \frac{c - 1}{\varepsilon_i(x)} \right) M(x, \zeta) G_{i} \left( \frac{c^{-1} - 1}{\varphi_i(x)} \right) = M(e_i^r(x), \zeta)
\]
(4.34)
for \(e_i^r(x) \in \mathcal{B}\) in (4.28). In the same way, the action of \(e_i^s\) on \((x, y) \in \mathcal{B}^2\) in (4.29) is represented by
\[
G_{i} \left( \frac{c - 1}{\varepsilon_i(x, y)} \right) M(x, \zeta) M(y, \zeta) G_{i} \left( \frac{c^{-1} - 1}{\varphi_i(x, y)} \right) = M(e_i^s(x), \zeta) M(e_i^s(y), \zeta).
\]
(4.35)
By using the formulas in example 4.15, one can also define the action of \(e_i^r\) for the general multiple product case. Through these examples, we observe that the product of matrices \(M(x^{(1)}, \zeta) \cdots M(x^{(L)}, \zeta)\) corresponds to the product of geometric crystals \((x^{(1)}, \ldots, x^{(L)}) \in \mathcal{B}^L\).

It is easy to see that equation (4.25) is equivalent to the matrix equation
\[
M(x, \zeta) M(y, \zeta) = M(\tilde{y}, \zeta) M(\tilde{x}, \zeta).
\]
(4.36)
Due to the presence of the spectral parameter $\zeta$, its non-trivial solution is unique. This characterizes the birational $R$ as the unique intertwiner (i.e. the operator that interchanges the order of the product) of the geometric crystals. For $x = (x_1, \ldots, x_{n+1}) \in B$, we set $\ell(x) = x_1 \cdots x_{n+1}$. The uniqueness of the solution to (4.36) can be verified as a consequence of the following.

**Proposition 4.16.** Suppose $M(x, \zeta)M(y, \zeta) = M(x', \zeta)M(y', \zeta)$ for $\ell(x) = \ell(x') \neq \ell(y) = \ell(y')$. Then, $x = x'$, $y = y'$.

**Proof.** We define $\overline{M}(x, \zeta) = (1 - \zeta \ell(x))M(x, \zeta)$ to avoid a singularity of $M(x, \zeta)$ at $\zeta = \ell(x)^{-1}$. Now the relation $\overline{M}(x, \zeta)\overline{M}(y, \zeta) = \overline{M}(x', \zeta)\overline{M}(y', \zeta)$ is supposed to be satisfied under the condition $\ell(x) = \ell(x') \neq \ell(y) = \ell(y')$. It is easy to see that the matrix elements of $\overline{M}(x, \zeta)$ are given by

$$
\overline{M}(x, \zeta)_{ij} = \begin{cases} 
\prod_{k=i}^{j} x_k & \text{for } i \geq j, \\
\zeta \left( \prod_{k=i}^{j} x_k \right) \left( \prod_{k=i}^{n} x_k \right)^{-1} & \text{for } i < j.
\end{cases}
$$

(4.37)

Note that the rank of the matrix $\overline{M}(x, \zeta)$ reduces to 1 when $\zeta = \ell(x)^{-1}$ or more precisely $\overline{M}(x, \zeta)^{-1}_{ij} = (\ell(x))^{-1} \left( \prod_{k=i}^{j} x_k \right) \left( \prod_{k=i}^{n} x_k \right)^{-1}$ for any $i, j$. Thus, the relation $\overline{M}(x, \zeta)\overline{M}(y, \zeta) = \overline{M}(x', \zeta)\overline{M}(y', \zeta)$ at $\zeta = \ell(x)^{-1}$ yields the condition $\left( \prod_{k=i}^{n} x_k \right)^{-1}$ for any $i$ and with some constant $\alpha$, forcing $x_i = x'_i$ for any $i$. In the same way, we obtain $y = y'$ by taking $\zeta = \ell(y)^{-1}$ in the relation. \hfill \Box

Now we show that the birational $R$ is the intertwiner of the geometric crystals.

**Proposition 4.17.** $Re'_i = e'_i R$.

**Proof.** Let $R(x, y) = (\tilde{y}, \tilde{x})$, $e'_i R(x, y) = ((\tilde{y})', (\tilde{x})')$, $e'_i(x, y) = (x', y')$ and $Re'_i(x, y) = (y', x')$. Then, we have

$$
M((\tilde{y}), \zeta)M((\tilde{x}), \zeta) = M(x', \zeta)M(y', \zeta)
$$

$$
= G_i \left( e^{-1} \ell(x, y) \right) M(x, \zeta)M(y, \zeta) G_i \left( e^{-1} \ell(x, y) \right) = G_i \left( e^{-1} \ell(\tilde{y}, \tilde{x}) \right) M((\tilde{y}), \zeta)M((\tilde{x}), \zeta) G_i \left( e^{-1} \ell(\tilde{y}, \tilde{x}) \right)
$$

Here, we used $\ell(\tilde{y}, \tilde{x}) = \ell_i(x, y)$ and $\phi_i(\tilde{y}, \tilde{x}) = \phi_i(x, y)$ which are verified by (4.25). By proposition 4.16, we have $\tilde{y}' = (\tilde{y})', \tilde{x}' = (\tilde{x})'$. We show that the birational $R$ satisfies the Yang–Baxter equation. \hfill \Box

**Proposition 4.18 [79, theorem 2.2].** The birational $R$ satisfies (4.24).

**Proof.** Let $R_1 R_2 R_1(x, y, z) = (z', y', x')$ and $R_2 R_1 R_2(x, y, z) = (z'', y'', x'')$. By proposition 4.11 and since (4.25) is equivalent to (4.36), we have

$$
M(z', \zeta)M(y', \zeta)M(x', \zeta) = M(x, \zeta)M(y, \zeta)M(z, \zeta) = M(z'', \zeta)M(y'', \zeta)M(x'', \zeta)
$$

(4.38)

By an obvious extension of proposition 4.16, this leads to $x' = x'', y' = y'', z' = z''$. \hfill \Box
4.3.4. Bilinearization. The birational $R$ is equivalent to a system of bilinear difference equations of Hirota type [51]. To see this, introduce the functions $\tau_i^j (1 \leq J \leq 4, i \in \mathbb{Z}_{n+1})$ and the parameters $\lambda_i, \kappa_i$, and make the change of variables
\[
\begin{align*}
\tau_i^{-1} &= \lambda_i \delta \tau_i^2 / \delta \tau_i^4, \\
\tilde{y}_i^{-1} &= \kappa_i \delta \tau_i^2 / \delta \tau_i^4,
\end{align*}
\]
(4.39)
with $\delta \tau_i^4 = \tau_i^4 / \tau_{i-1}^4$. In order to memorize relations (4.25), it is useful to draw the following vertex diagram and regard the tau functions as residing in the quadrants:
\[
\begin{array}{c|c|c|c}
| & x & \tau^2 & y \\
|---|---|---|---|
| y & | \tau^1 & |
| \tau^3 & - & \tilde{x} & |

Then, the former relation in (4.25) is automatically satisfied and the latter is translated into
\[
\lambda_i \tau_i^2 \tau_i^4 - \kappa_i \tau_i^2 \tau_i^4 = \alpha \tau_i^2 \tau_i^4
\]
(4.41)
for any nonzero parameter $\alpha$ independent of $i$. The birational map $R : (x, y) \mapsto (\tilde{y}, \tilde{x})$ is induced by an automorphism $\tau_i^2 \leftrightarrow \tau_i^4, \lambda_i \leftrightarrow \kappa_i, \alpha \mapsto -\alpha$ of (4.41). Equation (4.41) is a version of the so-called Hirota–Miwa (non-autonomous discrete KP) equation.

4.4. General solution. Recall that the KKR map $\phi^{-1}$ (section 3.2) transforms a rigged configuration into a highest path. It turns out that its image allows for an explicit formula in terms of ultradiscrete tau functions. In view of the remarks after (3.23), this yields the general solution of the BBS time evolution equation (4.15) corresponding to an arbitrary initial condition.

To formulate the ultradiscrete tau function, it is convenient to regard a rigged configuration as a multiset i.e. a set with multiplicity of each element taken into account
\[
S = \{(a_i, l_i, J_i) \in \{1, 2, \ldots, n\} \times \mathbb{Z}_{\geq 1} \times \mathbb{Z}_{\geq 0} \mid i = 1, 2, \ldots, N\},
\]
(4.42)
where $N \geq 0$ is arbitrary and each triplet $s = (a, l, r)$ signifies a string having color $a$, length $l$ and rigging $r$. This fact will be denoted by $\text{cl}(s) = a, \text{lg}(s) = l$ and $\text{rg}(s) = r$. $S$ is a rigged configuration if $\text{rg}(s) \leq p_{\text{cl}(s)}$ is satisfied for all $s \in S$, where $p_{\text{cl}(s)}$ is defined in (3.9).

For a rigged configuration $S (4.42)$, let $T \subseteq S$ be a (possibly empty) subset of $S$. We allow the fact that $T$ is no longer a rigged configuration in general. Introduce the piecewise-linear functions $c_{k,a}(T) (0 \leq k \leq L$ and $1 \leq a \leq n + 1)$ by
\[
c(T) = \frac{1}{2} \sum_{s, t \in T} C_{\text{cl}(s), \text{cl}(t)} \min(\text{lg}(s), \text{lg}(t)) + \sum_{s \in T} \text{rg}(s),
\]
(4.43)
\[
c_{k,a}(T) = c(T) + \sum_{s \in T, \text{cl}(s) = a} \text{lg}(s) - k \sum_{s \in T, \text{cl}(s) = 1} 1,
\]
(4.44)
where $C_{a,b} = 2 \delta_{a,b} - \delta_{a-b,1}$ is an element of the Cartan matrix $(C_{a,b})_{1 \leq a, b \leq n}$ of $\mathfrak{sl}_{n+1}$. ($L$ will be the length of the corresponding path.) By definition, the second term in $c_{k,a}(T)$ is 0 when $a = n + 1$. Obviously we have $c(\emptyset) = c_{k,a}(\emptyset) = 0$. The quantity $c(S)$ is known as

9 Colors $1, 2, \ldots, n$ of strings in rigged configurations should not be confused with the colors of balls in the BBS.
the cocharge of the rigged configuration $S$ [42]. The ultradiscrete tau function is a $\mathbb{Z}_{\geq 0}$-valued piecewise-linear function $\tau_{k,a} = \tau_{k,a}(S)$ on $S$ defined by (0 $\leq k \leq L$)
\[
\tau_{k,a} = - \min_{T \subseteq S} (c_{k,a}(T)) \quad (1 \leq a \leq n+1),
\]
(4.45)
\[
\tau_{k,0} = \tau_{k,n+1} - k.
\]

**Example 4.19.** $\tau_{0,n+1} = - \min_{T \subseteq S}(c(T))$ for $S$ (4.42) with $N = 1$, 2, 3 is given by
\[
\begin{align*}
\tau_{0,0+1} &= - \min(0, \xi_1), \\
\tau_{0,2+1} &= - \min(0, \xi_1, \xi_2, \xi_1 + \xi_2 + A_{1,2}), \\
\tau_{0,3+1} &= - \min(0, \xi_1, \xi_2, \xi_3, \xi_1 + \xi_2 + A_{1,2}, \xi_1 + \xi_3 + A_{1,3}, \xi_2 + \xi_3 + A_{2,3}),
\end{align*}
\]
where we have used the shorthand $\xi_i = l_i + J_i$ and $A_{i,j} = C_{a,a_i} \min(l_i, l_j)$.

In general, the minimum (4.45) for $S$ (4.42) extends over $2^N$ candidates and reminds us of the structure of tau functions in the theory of solitons [59]. In fact, (4.45) can be deduced from the tau functions in the discrete KP hierarchy by ultradiscretization with an elaborate turning of parameters between KP solitons and rigged configurations [53, section 5].

In section 3.3, we have seen that rigged configurations undergo linear time evolution (3.19). In the present notation, it is rephrased as
\[
S = \{(a_i, l_i, J_i)\}^{N}_{i=1} T_i(S) := \{(a_i, l_i, J_i + \delta_{1,a_i} \min(l_i, l_j))\}.
\]
(4.46)

**Theorem 4.20.** Let $b_k \otimes \cdots \otimes b_k = \phi^{-1}(S)$ be the image (highest path) of a rigged configuration $S$ under the KKR map $\phi^{-1}$.

(i) [53, theorem 2.1] $b_k = (x_1, \ldots, x_{n+1}) \in B_1 (2.17)$ $|a=1$ is expressed as
\[
x_k,a = \tau_{k,a} - \tau_{k-1,a-1} + \tau_{k-1,a-1}.
\]
(4.47)

(ii) [53, proposition 5.1] Denote by $\tau_{k,a}$ the ultradiscrete tau function associated with $T_{\infty}(S)$ defined by (4.46). (Thus, $\tau_{k,1} = \tau_{k,n+1}$. ) Then, the following ultradiscrete Hirota–Miwa equation is satisfied:
\[
\tau_k,a - 1 + \tau_{k-1,a} = \max(\tau_{k,d} + \tau_{k-1,a-1}, \tau_{k-1,a-1} + \tau_{k,a} - 1) \quad (2 \leq a \leq n+1).
\]
(4.48)

(iii) [53, theorem 4.9] Define $p = \cdots \otimes x^0_k \otimes x^0_{k+1} \otimes \cdots$ by $x^0_k = b_k$ if $1 \leq k \leq L$ and $x^0_k = 1$ otherwise. Let $\rho_k^0$ be the number of balls specified from $p$ as in (4.12). Then, $\tau_{k,a} = \rho_k^0$ holds for $1 \leq k \leq L, 1 \leq a \leq n+1$.

Theorem 4.20 is known to hold also for extended rigged configurations (remark 3.6) and nonhighest paths [53, section 7]. In view of the inverse scattering method (section 3.3), it provides the explicit piecewise-linear formula describing the BBS under any time evolution.

**Remark 4.21.** Let $N_a$ be the number of strings in a rigged configuration $S$ having color $a$. The soliton/string correspondence (3.22) tells us that $S$ describes the $N_a$-soliton states of the BBS. On the other hand, $\tau_{a}(S)$ is an ultradiscretization of an $N = N_1 + \cdots + N_a$-soliton solution of the discrete KP equation [53]. For $n > 1$, the ‘extra’ $N_2 + \cdots + N_n$ solitons in KP specify the internal labels of the BBS solitons.

The cocharge mentioned under (4.44) is related to the energy of a path, which involves the energy function $H$ (2.33) as a building block. See, for example, [60, 61, 65]. In this context, ultradiscrete tau functions are combinatorial analogs of corner transfer matrices in solvable lattice models [6], and (4.47) is regarded as the formula for a ‘one-point function’.

These features and the insights gained in section 3.3 are summarized in the following table. One can compare the format of the solutions of the BBS coming from the two basic tools in quantum integrable systems, Bethe ansatz and corner transfer matrices.
5. Periodic BBS

5.1. Basic features

In this section, we restrict ourselves to the \( \widehat{sl}_2 \) case and consider the BBS with the periodic boundary condition, which we call periodic BBS for short [56, 57, 81, 82]. An example of the time evolutions of this system appeared in section 1. Compared with the infinite system, there are many interesting features in the periodic BBS which come from the finiteness of its phase space. For an attempt to generalize our formalism to the case of the periodic \( \widehat{sl}_{n+1} \) BBS, see [55].

Let us recall the formalism in section 2.3 which is based on the crystal base theory. In the case of \( \widehat{sl}_2 \), the vertex diagrams for combinatorial 

\[
(2.37) \quad o n \quad B_l \otimes B_1 \;
\]

look like those in (2.14). Let \( L \) be the system size and \( M (\leq L/2) \) be the number of balls. Consider the diagram (2.39) with not necessarily large \( L \).

To attain the periodic boundary condition, we want to find \( v' \in B_l \) such that \( v' = v \). See (2.15) for an example. In general, \( v' \) is a function of \( v \in B_l \) and \( p := b_1 \otimes \cdots \otimes b_L \in (B_1)^{\otimes L} \). Hence, we can denote it by \( v' = v'(v, p) \).

Proposition 5.1 [56, proposition 2.1]. For any \( p \in P_L \) under the condition \( \# \{ i | b_i = 2 \} < L/2 \), the solution \( v \in B_l \) to the equation \( v'(v, p) = v \) is unique and is given by \( v = v'(u_l, p) \), where \( u_l = 1 \cdots 1 \in B_l \).

Let \( v_l(p) = v'(u_l, p) \). By setting \( v = v' = v_l(p) \) in (2.39) we define the time evolution operator \( T_l \) by relation (2.43). That is, we have

\[
(5.2) \quad v_l(p) \otimes p \simeq T_l(p) \otimes v_l(p),
\]

as elements of \( B_l \otimes (B_1)^{\otimes L} \simeq (B_1)^{\otimes L} \otimes B_l \). We note that (5.2) is a periodic version of the Lax equation (2.45). In particular, \( T_1 \) yields a cyclic shift by one unit cell to the right. The evolution by \( T_\infty \) admits the description without a carrier given in section 1, which is also equivalent to the 'arc rule' in [81].

Remark 5.2. In section 5.1, we restrict ourselves to the case \( M < L/2 \) for simplicity. However, our formalism of the periodic BBS based on the crystal base theory also enables one to treat the case \( M \geq L/2 \) [56].

The energy associated with \( T_l \) is defined by (2.44) with \( v_0 = v_l(p) \), where the values of the energy function are given by \( H = 0 \) for the bottom-right diagram in (2.14) and \( H = 1 \) otherwise.

In what follows, we write for example \( \begin{array}{c} 1 \\ 2 \\ 1 \\ 2 \end{array} \) simply as 1212.

Example 5.3. The time evolutions of \( p = 2221121211111 \) by \( T_l \) with \( l \geq 3 \), \( T_2 \) and \( T_1 \):

| t=0 | 222...2... | 222...2... | 222...2... |
|-----|-------------|-------------|-------------|
| t=1 | 222...2...  | 222...2...  | 222...2...  |
Theorem 5.4 [56, theorem 2.2]. The commutativity \( T_l T_k(p) = T_k T_l(p) \) and the conservation of the energy \( E_l(T_k(p)) = E_l(p) \) hold.

Proof. Let \( R(v_k(T_l(p)) \otimes v_l(p)) = v_l(p) \otimes v_k(T_l(p)) \). See the following diagram:

\begin{array{c}}}

where the Yang–Baxter relation is used to move the symbol ‘\( \times \)’ for the \( R \) from the left to the right. Consider what \( x, y, z \) and \( w \) should be. Since \( R(v_k(T_l(p)) \otimes v_l(p)) = v_l(p) \otimes v_k(T_l(p)) \), we have \( x = v_k(T_l(p)) \) and \( y = v_l(p) \). Hence, by proposition 5.1 the equality \( v_k(T_l(p)) = v_k(p) \) holds. Thus, \( z = T_k(p) \). Then, again by proposition 5.1, the equality \( v_l(p) = v_l(T_k(p)) \) holds, and we have \( w = T_l(T_k(p)) \). Hence, \( T_l(T_k(p)) = T_l(T_k(p)) \). For a proof of the conservation of the energy, see [56, theorem 2.2]. \( \square \)

5.2. Linearization and general solution

Here we construct action-angle variables of the periodic BBS, solve the initial value problem and present an explicit formula for \( N \)-soliton solutions in terms of tropical Riemann theta function. These results were firstly obtained in [50, 56].

5.2.1. Action variable. We are going to introduce the action variable of a state. It is equivalent to the list of amplitudes of solitons contained in a state, which is the conserved quantity. Recall that a state \( p = b_1 b_2 \ldots b_L \) is highest if condition (3.4) is satisfied. It is elementary to show that any state in \( \mathcal{P}_L \) can be made highest by a cyclic shift. Namely, there exists a highest state \( p_* \in \mathcal{P}_L \) and \( d \in \mathbb{Z} \) such that \( p = T_l^d(p_*) \). Given \( p \), such a pair \((d, p_*)\) is not necessarily unique. Nevertheless one can show

Proposition 5.5 [56, proposition 3.3], (i) Let \( \mu \) be the configuration of the rigged configuration \( \phi(p_*) \). (Namely, \( \mu \) is the Young diagram denoted by \( \mu^{(1)} \) in section 3.2.) Then, \( \mu \) is independent of the not necessarily unique choice of \((d, p_*)\).
(ii) The energy $E_l$ of $p$ is related to $\mu$ via

$$E_l(p) = \text{number of cells in the left } l \text{ columns of } \mu.$$  \hfill (5.3)

Due to (i), the Young diagram $\mu$ is uniquely determined from a state $p$. We denote it by $\mu^*(p)$ and call it the action variable of $p$. Due to (ii), it is a conserved quantity, namely $\mu^*(T_l(p)) = \mu^*(p)$ holds for any $l$. Let $m_k = m_k(p)$ be the number of length $k$ rows in the Young diagram $\mu^*(p)$. Then, (5.3) is rephrased by the same formula as (2.47):

$$E_l(p) = \sum_{k \geq 1} \min(l, k)m_k.$$ \hfill (5.4)

In the context of the KKR bijection, $m_k$ is the number of length $k$ rows in the Young diagram $\mu^*(p)$. On the other hand, $m_k$ is the number of amplitude $k$ solitons contained in $p$. This is another manifestation of the soliton/string correspondence, which was also observed earlier in the BBS on an infinite lattice in (3.22). We introduce the isolevel set of states characterized by the action variable

$$\mathcal{P}_L(\mu) = \{ p \in \mathcal{P}_L \mid \mu^*(p) = \mu \}$$ \hfill (5.5)

for any Young diagram $\mu$ such that $|\mu| \leq L/2$.

**Example 5.6.** Take $p = 221122111212211122211122 \in \mathcal{P}_{19}$. It can be expressed as cyclic shifts of highest paths as $p = T_2^c(p_+) = T_3^c(p'_+) = T_4^c(p''_+)$, where $p_+ = 1122112221112221222111222122$, $p'_+ = 1112122112212211122122111221222122$, and $p''_+ = 111221221112212211122122111221222122$. Their image by the KKR map $\phi$ is given by

$$p_+ \xrightarrow{\phi} \begin{array}{c|c|c|c} 1 & 1 & 1 & 1 \\ \hline 0 & 0 & 0 & 0 \\ \hline 3 & 3 & 3 & 3 \\ \hline \end{array}, \quad p'_+ \xrightarrow{\phi} \begin{array}{c|c|c|c} 1 & 1 & 1 & 1 \\ \hline 3 & 3 & 3 & 3 \\ \hline 0 & 0 & 0 & 0 \\ \hline \end{array}, \quad p''_+ \xrightarrow{\phi} \begin{array}{c|c|c|c} 1 & 1 & 1 & 1 \\ \hline 3 & 3 & 3 & 3 \\ \hline 0 & 0 & 0 & 0 \\ \hline \end{array}.$$  

They all lead to $\mu^*(p) = (3, 2, 2, 1, 1)$.

**Example 5.7.** The isolevel sets $\mathcal{P}_6(\mu)$ with $|\mu| = 3$ are given by

$\mathcal{P}_6((1, 1, 1)) = \{121212, 212121\}$,

$\mathcal{P}_6((3)) = \{111222, 211122, 221112, 222111, 122211, 112221\}$,

$\mathcal{P}_6((2, 1)) = \{112212, 212112, 221121, 122121, 112212, 211212, 221112, 212112, 122112, 121212, 212211, 121221\}$.

**5.2.2. Angle variable.** Let us observe example 5.6. Recall that in the infinite system, the time evolution $T_1$ is the uniform shift of all the riggings by 1. See (3.19). If we adopt the same feature also in the periodic BBS, the following identification should be made for the ‘periodic version’ of the rigged configuration:

$$\begin{array}{c|c|c|c} 1 & 1 & 1 & 1 \\ \hline 3 & 3 & 3 & 3 \\ \hline 9 & 9 & 9 & 9 \\ \hline \end{array} \equiv \begin{array}{c|c|c|c} 1 & 1 & 1 & 1 \\ \hline 3 & 3 & 3 & 3 \\ \hline 9 & 9 & 9 & 9 \\ \hline \end{array}, \quad \begin{array}{c|c|c|c} 1 & 1 & 1 & 1 \\ \hline 16 & 16 & 16 & 16 \\ \hline 13 & 13 & 13 & 13 \\ \hline \end{array} \equiv \begin{array}{c|c|c|c} 1 & 1 & 1 & 1 \\ \hline 16 & 16 & 16 & 16 \\ \hline 13 & 13 & 13 & 13 \\ \hline \end{array}.$$ \hfill (5.7)

Here we have attached the vacancy $p_i$ on the left of the block of length $i$ strings. The riggings are no longer bounded by it. The basic idea in constructing angle variables is to introduce an appropriate equivalent relation among such extended riggings.
We proceed to the precise definition. Consider the isolevel set \( \mathcal{P}_L(\mu) \) with \( \mu = (i^m_1 \cdots i^m_q) \). Here \( i_1 < \cdots < i_q \) are the lengths of the rows in \( \mu \) and \( m_j \) is the multiplicity of \( i_j \). For instance \( \mu = (3^1 2^2 1^2) \) in (5.7). We set

\[
\mathcal{I} = \{i_1 < \cdots < i_q\}, \quad p_j = L - 2 \sum_{i \in \mathcal{I}} \min(j, i)m_i \quad (j \in \mathbb{Z}_{\geq 0}), \tag{5.8}
\]

where the latter is the vacancy \( p_j^{(1)} \) (3.9) with \( n = 1 \). Recall that a rigged configuration \((\mu, J)_L \) is the data in which the vicinity of the block of length \( i \) strings looks as

\[
J = (J_{i,\alpha}), \quad i \in \mathcal{I}, \quad 1 \leq \alpha \leq m_i, \quad 0 \leq J_{i,1} \leq \cdots \leq J_{i,m_i} \leq p_i. \tag{5.9}
\]

We extend the integer sequence \( J_{i,\alpha} \) from \( 1 \leq \alpha \leq m_i \) to \( \alpha \in \mathbb{Z} \) by imposing the quasi-periodicity as

\[
J_{i,\alpha + m} = J_{i,\alpha} + p_i \quad (\alpha \in \mathbb{Z}). \tag{5.10}
\]

The resulting sequence will be denoted by \( \mathbf{J} = (J_{i,\alpha})_{(i, \alpha) \in \mathcal{I} \times \mathbb{Z}} \) and called a quasi-periodic extension of the rigging \( J \). (Indices will be suppressed as \( \mathbf{J} = (J_{i,\alpha}) \).) By definition, \( \mathbf{J} \) ranges over the set

\[
\tilde{\mathbf{J}}_L(\mu) = \mathbf{\tilde{\Lambda}}(m_i, p_i), \tag{5.11}
\]

where \( L \)-dependence enter (5.11) via \( p_i \). Now we introduce the equivalence relation on \( \tilde{\mathbf{J}}_L(\mu) \). For \( k \in \mathcal{I} \), define \( \sigma_k \) by

\[
\sigma_k : \tilde{\mathbf{J}}_L(\mu) \rightarrow \tilde{\mathbf{J}}_L(\mu); \quad (J_{i,\alpha}) \mapsto (J_{i,\alpha + m} + 2 \min(i, k)). \tag{5.13}
\]

Let \( \mathcal{A} \) be the abelian multiplicative group generated by \( \sigma_{i_1}, \ldots, \sigma_{i_q} \). Define

\[
\mathbf{J}_L(\mu) = \tilde{\mathbf{J}}_L(\mu)/\mathcal{A}, \tag{5.14}
\]

\(^{10}\) The \( i_1, \ldots, i_q \) here and in section 6.3 will denote the amplitude of solitons. They should not be confused with the ones in section 3 like \( p = i_1 \cdots i_L \) or in (3.4) and (3.7).
which is the set of equivalence classes of \( \tilde{J}_L(\mu) \) under \( \mathcal{A} \). The image \([\mathbf{J}] \in J_L(\mu)\) of \( \mathbf{J} \in \tilde{J}_L(\mu) \) will also be written as \( \mathbf{J} \) for simplicity unless emphasis is preferable. Elements of \( J_L(\mu) \) are called angle variables.

Angle variables are also depicted as (5.9). Actually, infinitely many such diagrams that are transformable by \( \mathcal{A} \) all correspond to a single angle variable. For instance in (5.7), if the leftmost one is \([\mathbf{J}]\), then the middle and the rightmost ones are \([\sigma_2(\mathbf{J})]\) and \([\sigma_1\sigma_2^3(\mathbf{J})]\), respectively.

We introduce the time evolution \( T_l \) (\( l \geq 1 \)) on \( \tilde{J}_L(\mu) \) by

\[
T_l : \tilde{J}_L(\mu) \rightarrow \tilde{J}_L(\mu) : (J_{l,\alpha}) \mapsto (J_{l,\alpha} + \min(i, l)),
\]

and denote its induced action on \( J_L(\mu) \) also by \( T_l \). Obviously, \( T_l \) is linear and commutative. In particular, we use the abbreviation \( T_l^{d}(\mathbf{J}) = \mathbf{J} + d \) for the uniform shift. Readers are highly recommended to check that \( (\prod_{i \in \mathbb{Z}} \sigma_i^m) (\mathbf{J}) = \mathbf{J} + L \in \tilde{J}_L(\mu) \), which implies that any angle variable is invariant under \( T_l^{d} \) as it should.

5.2.3. Linearization of time evolution. Let us assign an angle variable to each state in the isolevel set \( \mathcal{P}_L(\mu) \). Namely, we are going to construct a direct scattering map \( \Phi : \mathcal{P}_L(\mu) \rightarrow J_L(\mu) \). We do this by suitably adapting the KKR map \( \phi \) to the periodic setting. Let \( \mathcal{P}_L^+ = \{ p \in \mathcal{P}_L(\mu) \mid p : \text{highest} \} \) be the subset of \( \mathcal{P}_L(\mu) \) consisting of highest paths. We consider the following scheme:

\[
\Phi : \mathcal{P}_L(\mu) \rightarrow \mathbb{Z} \times \mathcal{P}_L^+ \rightarrow \tilde{J}_L(\mu) \rightarrow J_L(\mu)
\]

First arrow: pick any \((d, p_+)\) such that \( p = T_l^{d}(p_+) \). Second arrow: apply the KKR map \( \phi(p_+) = (\mu, J)_L \) and quasi-periodically extend the so-obtained rigging \( J \) to \( \mathbf{J} \) followed by a uniform shift by \( d \). Third arrow: take the image in \( \tilde{J}_L(\mu) \) (identified by \( \mathcal{A} \)). In order to make sense of scheme (5.16) as a definition of the map \( \Phi \), the non-uniqueness in the first arrow must be canceled in the identification in the third arrow. It was indeed the case in example (5.7). Here comes the main result of this section.

**Theorem 5.8** [56, theorem 3.11]. \( \Phi \) is well defined, bijective and makes the following diagram commutative:

\[
\begin{array}{ccc}
\mathcal{P}_L(\mu) & \xrightarrow{\Phi} & J_L(\mu) \\
\downarrow T_l & & \downarrow T_l \\
\mathcal{P}_L(\mu) & \xrightarrow{\Phi} & J_L(\mu).
\end{array}
\]

Here, \( T_l \) on the left and right sides are defined by (5.2) and (5.15), respectively.

The commutative diagram (5.17) is the periodic version of (3.17). According to theorem 5.8, the nonlinear time evolution on \( \mathcal{P}_L(\mu) \) is transformed to a straight motion on \( J_L(\mu) \). This is a characteristic feature in finite-dimensional integrable systems, where the dynamics is linearized, via what is called the eigenvector map, on Jacobian variety (or more precisely, abelian variety). In our setting here, the modified KKR map \( \Phi \) and the set of angle variables \( J_L(\mu) \) play the analogous roles to them. In section 6.3, we will study this feature with tropical geometry, and see that \( J_L(\mu) \) corresponds to the lattice points of some tropical abelian variety.

Theorem 5.8 led to the first complete solution of the initial value problem of the periodic BBS. It is obtained by going along the commutative diagram (5.17) as \( T_l^{N} = \Phi^{-1} \circ T_l^{N} \circ \Phi \).

The variety of time evolutions \( T_1, T_2, \ldots \) is reflected in the corresponding velocity vectors in (5.15).
5.2.4. N-soliton solution. Let us present an explicit formula of the path \( p \) in example 5.6:

\[
T^5_3(p) = 122112211211221122.
\] (5.18)

The angle variable of \( p \) has been obtained in (5.7). Using the leftmost representation, we find

\[
\begin{align*}
p & \mapsto \begin{array}{c}
1 \\
3 \\
6 \\
10 \\
13 \\
15 \\
18 \\
22 \\
25 \\
28
\end{array} \\
\Phi & \mapsto \begin{array}{c}
3 \\
1 \\
2 \\
0 \\
13 \\
12 \\
19 \\
11 \\
5 \\
1
\end{array} \\
T^3_2 & \mapsto \begin{array}{c}
1 \\
2 \\
3 \\
18 \\
12 \\
8 \\
5 \\
3 \\
1 \\
0
\end{array} \\
\sigma_2 \sigma_5^2 & \mapsto \begin{array}{c}
2 \\
1 \\
0 \\
5 \\
3 \\
1 \\
8 \\
12 \\
18 \\
22
\end{array}
\end{align*}
\]

The vacancies are exhibited only in the leftmost diagram. The rightmost diagram is a rigged configuration and corresponds to the highest path \( p' = 112112211211221122 \). Therefore, the image of the rightmost angle variable by \( \Phi^{-1} \) is \( T^4_9(p') \) giving the rhs of (5.18).

As this example indicates, to compute the inverse image \( \Phi^{-1}(J) \), one first finds a representative of the angle variable \( J \) of the form (rigged configuration) + \( e \) with some \( e \in \mathbb{Z} \). Namely, one transforms \( J \) into \( \sigma(J) = J' + \epsilon \) with an appropriate element \( \epsilon \in \mathcal{A} \) so that \( J' \) becomes the quasi-periodic extension of some rigged configuration \((\mu, J')_L\). Then, one applies the KKR map \( \phi^{-1} \) to get a highest path \( p'_{\epsilon} \), as \( p'_{\epsilon} = \phi^{-1}((\mu, J')_L) \). Finally, the inverse image is obtained as \( \Phi^{-1}(J) = T^e_9(p'_{\epsilon}) \). The fact that these procedures are always possible and the result is unique is guaranteed by theorem 5.8. We note that the solution of the initial value problem based on the procedure called 10-elimination [57] is equivalent [43] to the preceding solution [56] explained here.

5.2.4. N-soliton solution. Let us present an explicit formula of the path \( p = \Phi^{-1}(J) \in \mathcal{B}^{gL} \) that corresponds to the given angle variable \( J \in \mathcal{J}(\mu) \). This is a combinatorial analog of the Jacobi inversion problem, and the result is indeed expressed in terms of the tropical Riemann theta function. For simplicity, we restrict ourselves to the case \( m_i = 1 \) for all \( i \in \mathcal{I} \). (See [54] for the general case, where the tropical Riemann theta function with rational characteristics is involved.) We retain notation (5.8), where the latter reduces to \( p_j = L - 2 \sum_{i \in \mathcal{I}} \min(j, i) \).

The angle variable \( J = (J_{(j,\alpha) \in \mathcal{I} \times \mathcal{I}}) \) can be presented simply as a \( g \)-dimensional vector \( J = (J_i)_{i \in \mathcal{I}} \) with \( J_i = J_{i1} \) since the other components are specified as \( J_{i\alpha} = J_i + (\alpha - 1)p_{ij} \) by the quasi-periodicity. It is easy to translate the identification by (5.13) into this representation of \( J \), leading to the simple description

\[
\mathcal{J}(\mu) = \mathbb{Z}^g/F\mathbb{Z}^g, \quad F = (\delta_{ij} p_{ij} + 2 \min(i, j))_{i, j \in \mathcal{I}}.
\] (5.19)

The \( g \times g \) integer matrix \( F \) is positive definite and has the origin in the study of the Bethe equation at \( q = 0 \) [47]. We introduce the tropical Riemann theta function (definition 6.10)

\[
\Theta(Z; F) = \min_{w \in \mathbb{Z}^g} \{ \mathbf{n} \cdot \left( \frac{1}{2} F \mathbf{n} + Z \right) \} \quad (Z \in \mathbb{R}^g)
\] (5.20)

in which \( F \) is built in as the period matrix. We further introduce the \( g \)-dimensional vectors

\[
p = (p_i)_{i \in \mathcal{I}}, \quad h_i = (\min(i, 1))_{i \in \mathcal{I}},
\] (5.21)

where the latter is the velocity corresponding to \( T_i (5.15) \).

**Theorem 5.10** [50, theorem 3.3]. The state \( \Phi^{-1}(J) = b_1 b_2 \ldots b_L \) (\( b_j = 1, 2 \)) corresponding to the angle variable \( J \in \mathcal{J}(\mu) \) is expressed as \( \Theta(Z) = \Theta(Z; F) \)

\[
b_L = 1 - \Theta \left( J - \frac{p}{2} - k h_1 \right) + \Theta \left( J - \frac{p}{2} - (k - 1) h_1 \right)
+ \Theta \left( J - \frac{p}{2} - k h_1 + h_\infty \right) - \Theta \left( J - \frac{p}{2} - (k - 1) h_1 + h_\infty \right).
\] (5.22)
The time evolution by $T_l$ is obtained just by replacing $J$ with $J + h_l$. Thanks to the quasi-periodicity (6.6), $b_k$ is invariant under the change $J \mapsto J + FZ$. The invariance $b_k = b_{k+iL}$ is due to $Fh_1 = Lh_1$.

**Remark 5.11.** The matrix $F$ (5.19) will be related to the period matrix $\Omega$ (6.17) of the tropical spectral curve of the tropical periodic Toda lattice at proposition 6.21.

5.3. Decomposition into a torus

5.3.1. Introduction. Let us discuss the structure of the isolevel set of the periodic BBS. Recall the definition of the isolevel set $P_L(\mu)$ in (5.5). We use the notations $\mu = (i_{m_1} \ldots m_{l_1}), I, p_j$ in section 5.2. In contrast to the tropicalization of the periodic discrete Toda lattice in section 6.2 where the isolevel set $J_C$ given by (6.14) is isomorphic to a real torus $\mathbb{R}^g/\Omega_1$, the set $P_L(\mu)$ is a finite set. As we have shown in theorem 5.8, the set $P_L(\mu)$ is identified with the set $J_L(\mu)$ which was defined as a quotient set (5.14).

The set $P_L(\mu)$ can be regarded as a graph in the sense of graph theory. Let $T$ be the abelian multiplicative group generated by $T_1, T_2, \ldots$. Then, $T$ acts on the isolevel set $P_L(\mu)$. If one represents the elements of $P_L(\mu)$ by nodes and the actions of the time evolutions by arrows, then one has a colored oriented graph. The graph for $P_L(\mu)$ has usually several connected components. From the viewpoint of the group action, we say that the isolevel set $P_L(\mu)$ decomposes into $T$-orbits.

To begin with, let us illustrate a few simple examples. First let us assume $m_j = 1$ for all $j \in I$. Then, we have $J_L(\mu) = \mathbb{Z}^g/\Omega_1$ (5.19) which is the set of all integer points on the torus $\mathbb{R}^g/\Omega_1$. We will call $\mathbb{Z}^g/\Omega_1$ itself a ($g$-dimensional) torus in short.

**Example 5.12.** The isolevel set $P_5((2))$ is depicted as follows:

\[
\begin{array}{cccc}
22111 & 21112 & 12211 & 11221 \\
11221 & 12112 & 12211 & 11221 \\
\end{array}
\]

Here the actions of $T_1$ and $T_2$ are represented by thin and thick arrows, respectively. Note that $P_5((2)) \simeq J_5((2)) = \mathbb{Z}/5\mathbb{Z}$. The velocity vectors (5.21) are given by $h_1 = (1)$ and $h_2 = (2)$ which reflect the relation $T_2 = (T_1)^2$ on this isolevel set.

Now we consider the case with $m_j > 1$ where the graph for $P_L(\mu)$ has indeed several connected components. Let

$$\Sigma(p) = \{p' \in P_L(\mu) | p' = gp \text{ for some } g \in T\} \subset P_L(\mu)$$

be the $T$-orbit of $p \in P_L(\mu)$.

**Example 5.13.** The graph for the isolevel set $P_6((1, 1))$ is depicted as follows:

\[
\begin{array}{cccc}
212111 & 212111 & 212111 & 212111 \\
211212 & 112121 & 112121 & 112121 \\
\end{array}
\]
5.3.2. Internal symmetry. The isolevel set in example 5.13 has two connected components with different sizes. The difference reflects the internal symmetry. If the state has a larger internal symmetry, then it belongs to a smaller connected component. Let us briefly discuss this notion here.

The internal symmetry of a BBS state is represented by an integer vector \( \mathbf{\gamma} = (\gamma_1, \ldots, \gamma_n) \in (\mathbb{Z}_{\geq 0})^{n} \). We demonstrate how one can read off \( \mathbf{\gamma} \) from \( p \). Given \( p \in \mathcal{P}_L(\mu) \), there exists a highest path \( p_+ \) and \( d \in \mathbb{Z} \) such that \( T^d_{p+} = p \). By the KKR map in section 3.2, a rigged configuration is constructed from \( p_+ \) as \( \phi(p_+) = (\mu, J) \) where \( J = (J_{i, \alpha})_{i \in I, 1 \leq \alpha \leq m_i} \). We adopt the quasi-periodic extension for the angle variables (5.10).

Now the integer \( J_{i, \alpha} \in \mathbb{Z} \) is defined as the largest common divisor of \( m_i \) and \( p_i \) such that

\[
J_{i, \alpha} = \frac{J_{i, \alpha}}{\gamma_i} \quad (\alpha \in \mathbb{Z}).
\]

(5.26)

Neither the action of \( \sigma_d \) in (5.13) nor that of \( T_j \) in (5.15) changes relation (5.26). Therefore, theorem 5.8 ensures that the internal symmetry of \( p \) is uniquely determined from the above procedure even if there is a non-unique choice of \( p_+ \).

Example 5.14. Take \( p = 1211211222 \), \( \tilde{p} = 1211121222 \in \mathcal{P}_{10} \) in example 5.17. They are already the highest. By the KKR map, we obtain the following rigged configurations:

\[
p \mapsto \begin{array}{c}
0 \\
4 \\
0 \\
0
\end{array}
\quad \tilde{p} \mapsto \begin{array}{c}
0 \\
4 \\
2 \\
0
\end{array}
\quad \text{(5.27)}
\]

In this example, one has \( g = 2, I = \{1, 3\} \); hence, \( \mathbf{\gamma} = (\gamma_1, \gamma_2) \). Note that the configuration implies \( m_i \) = 1 which imposes \( \gamma_2 = 1 \). While \( J_{1, \alpha} = J_{1, \alpha} + \frac{4}{2} \) for \( \tilde{p} \), no such symmetry exists for \( p \). Hence, one has \( \mathbf{\gamma} = (1, 1) \) for \( p \), and \( \mathbf{\gamma} = (2, 1) \) for \( \tilde{p} \).

Example 5.15. Take \( p = 12112211121221122111 \) with \( L = 24 \) which is already the highest. By the KKR map, we obtain the following rigged configuration:

\[
p \mapsto \begin{array}{c}
4 \\
6 \\
3 \\
0
\end{array}
\quad \text{(5.28)}
\]

Here we have \( g = 3 \) and \( I = \{1, 2, 3\} \); hence, \( \mathbf{\gamma} = (\gamma_1, \gamma_2, \gamma_3) \). Observe that \( J_{1, \alpha} = J_{1, \alpha} + \frac{12}{2} \) which implies \( \gamma_1 = 3 \). No such symmetry exists for \( J_{2, \alpha} \) (and \( J_{3, \alpha} \)). Hence, one has \( \mathbf{\gamma} = (3, 1, 1) \).

Let

\[
\mathcal{P}_{L, \gamma}(\mu) = \{ p \in \mathcal{P}_L(\mu) | \text{the internal symmetry of } p \text{ is } \mathbf{\gamma} \}.
\]

(5.29)

Then, we have \( \mathcal{P}_L(\mu) = \bigcup_{\gamma} \mathcal{P}_{L, \gamma}(\mu) \).
5.3.3. Connected component as a torus. So far the states of the periodic BBS are classified as
\[ \mathcal{P}_L \supset \mathcal{P}_L(\mu) \supset \mathcal{P}_L(\mu_\gamma) \supset \Sigma(p). \] (5.30)
Now we study the structure of a single connected component \( \Sigma(p) \). Let \( F_\gamma \) be a \( g \times g \) matrix defined as
\[ F_\gamma = F \cdot \text{diag}(\gamma^{-1}_1, \ldots, \gamma^{-1}_g). \] (5.31)
\[ F = (\delta_{ij} p_i + 2 \min(i, j) m_j)_{i, j \in I}. \] (5.32)
This matrix \( F_\gamma \) is a generalization of \( F \) in (5.19). Then, the structure of a connected component is stated as follows.

**Proposition 5.16** [69, theorem 2]. Every connected component of the isolevel set \( \mathcal{P}_L(\mu) \) has the structure of a \( g \)-dimensional torus \( \mathbb{Z}^g/F_\gamma \mathbb{Z}^g \). The time evolution \( T_\mu \) is realized as the straight motion with a constant velocity vector \( \mathbf{h}_t = (\min(i, 1))_{i \in I} \) on the torus.

This result may be viewed as an ultradiscrete analog of the classical Arnold–Liouville theorem [3].

**Example 5.17.** Take \( p = 1212111222, \tilde{p} = 1211121222 \in \mathcal{P}_{10} \). They belong to two distinct connected components of the level set \( \mathcal{P}_{10}(3, 1, 1) \). The \( T \)-orbits \( \Sigma(p) \) and \( \Sigma(\tilde{p}) \) have the structure of two-dimensional tori \( \mathbb{Z}^2/F_{1(1)} \mathbb{Z}^2 \) and \( \mathbb{Z}^2/F_{2(1)} \mathbb{Z}^2 \), respectively, where \( F_{1(1)} = \left( \begin{array}{cc} 8 & 2 \\ 4 & 6 \end{array} \right) \) and \( F_{2(1)} = \left( \begin{array}{cc} 4 & 2 \\ 2 & 6 \end{array} \right) \). They are depicted as follows:

The nodes within and on the edges of the parallelograms represent the states of the periodic BBS which belong to each of the connected components. Every pair of the parallel edges of each parallelogram should be identified. Thin and thick arrows represent the velocity vectors \( \mathbf{h}_1 \) and \( \mathbf{h}_2 \), respectively.

5.3.4. Fundamental period. The time evolution \( T_\mu \) is invertible and the isolevel set \( \mathcal{P}_L(\mu) \) is a finite set. Therefore, every path \( p \in \mathcal{P}_L(\mu) \) possesses the property \( T_{N_\mu}^N(p) = p \) for some integer \( N \geq 1 \). We say any such integer a period of \( p \). The minimum period is called the fundamental period of \( p \) and denoted by \( N_\mu(p) \). Every period is a multiple of the fundamental period. A formula for the fundamental period under any \( T_\mu \) was established in [56]. Here, we show a derivation of the formula based on proposition 5.16. Note that \( N_\mu(p) \) is common to all the states in one connected component. Hence, it is determined by the action variable \( \mu \) and the internal symmetry \( \gamma \).
To avoid double indices, we denote by \( f_j \) the \( j \)th column of the matrix \( F \) (5.32); hence, \( F = (f_1, \ldots, f_N) \). For any \( b \in \mathbb{Z}^N \), we define

\[
F(b) = (f_1, \ldots, f_{i-1}, b, f_{i+1}, \ldots, f_N).
\]

Let \( p \in \mathcal{P}_{L,Y}(\mu) \) be a state of the periodic BBS, and \( \Sigma(p) \simeq \mathbb{Z}^N/F_p \mathbb{Z}^N \). We define the least common multiple of nonzero rational numbers \( r_1, \ldots, r_n \) as

\[
\text{LCM}(r_1, \ldots, r_n) = \min \left| \mathbb{Z} \cap \mathbb{Z}r_1 \cap \cdots \cap \mathbb{Z}r_n \setminus \{0\} \right|.
\]

For instance, we let LCM(1/3, 2/3) be 2 rather than 2/3. Now we have

**Proposition 5.18** [56, theorem 4.9],

\[
\mathcal{N}_i(p) = \text{LCM} \left( \frac{\det F}{\gamma_i \det F[i|h_1]}, \ldots, \frac{\det F}{\gamma_i \det F[i|h_N]} \right),
\]

where we exclude any entries of the LCM such that \( \det F[i|h_1] = 0 \).

**Proof.** Proposition 5.16 implies that \( \mathcal{N}_i(p) \) is defined as the smallest positive integer \( N \) such that the following linear equation has an integer solution \( n = (n_1, \ldots, n_N) \in \mathbb{Z}^N \):

\[
Nh_i = F_p n.
\]

By demanding all these conditions on the expression \( n_j = N\gamma_i \det F_j[h_1]/\det F \) of the solution to (5.37), one obtains formula (5.36).

**Example 5.19.** Take \( p = 1212111222, \tilde{p} = 1211121222 \in \mathcal{P}_{10} \) in example 5.17. Then, \( \det F = \det \begin{pmatrix} \frac{5}{2} & \frac{7}{6} \\ \frac{1}{2} & \frac{3}{2} \end{pmatrix} = 40 \) and

\[
\det F_1[h_1] = \det \begin{pmatrix} 1 & 2 \\ 1 & 6 \end{pmatrix} = 4, \quad \det F_2[h_1] = \det \begin{pmatrix} 8 & 1 \\ 4 & 1 \end{pmatrix} = 4,
\]

\[
\det F_1[h_2] = \det \begin{pmatrix} 1 & 2 \\ 2 & 6 \end{pmatrix} = 2, \quad \det F_2[h_2] = \det \begin{pmatrix} 8 & 1 \\ 4 & 2 \end{pmatrix} = 12,
\]

\[
\det F_1[h_3] = \det \begin{pmatrix} 1 & 2 \\ 3 & 6 \end{pmatrix} = 0, \quad \det F_2[h_3] = \det \begin{pmatrix} 8 & 1 \\ 4 & 3 \end{pmatrix} = 20.
\]

Hence,

\[
\mathcal{N}_1(p) = \text{LCM}(40/4, 40/4) = 10, \quad \mathcal{N}_2(p) = \text{LCM}(40/2, 40/12) = 20,
\]

\[
\mathcal{N}_3(p) = \text{LCM}(40/20) = 2.
\]

For \( \tilde{p} \), one has \( \gamma_1 = 2, \gamma_5 = 1 \). Hence,

\[
\mathcal{N}_1(\tilde{p}) = \text{LCM}(40/8, 40/4) = 10, \quad \mathcal{N}_2(\tilde{p}) = \text{LCM}(40/4, 40/12) = 10,
\]

\[
\mathcal{N}_3(\tilde{p}) = \text{LCM}(40/20) = 2.
\]

For instance, one can deduce \( T_{20}^1(\tilde{p}) = \tilde{p} \) and \( T_{20}^1(p) \neq p \). One can easily check these results by using the figures in (5.33).

When the internal symmetry is trivial, i.e. \( \forall \gamma_i = 1 \), proposition 5.18 reduces to the result in [81].
5.3.5. Multiplicity of the torus and the structure of the isolevel set. The number of the elements of the isolevel set \( \mathcal{P}_L(\mu) \) is expressed by the formula [56]

\[
|\mathcal{P}_L(\mu)| = \det F \prod_{i \in \mathcal{I}} \left( \frac{p_i + m_i - 1}{m_i - 1} \right) \tag{5.41}
\]

\[
= \frac{L}{p_i} \prod_{i \in \mathcal{I}} \left( \frac{p_i + m_i - 1}{m_i} \right), \tag{5.42}
\]

where the \( g \times g \) matrix \( F \) is defined as (5.32). While the former expression (5.41) was first obtained in the context of Bethe ansatz [47, theorem 3.5], the latter one (5.42) was originally found as a formula for the cardinality \( |\mathcal{P}_L(\mu)| \) and proved by elementary combinatorial arguments [81, proposition 2.2]. Their equivalence is due to the relation \( \det F = p_{i_1} \cdots p_{i_{\ell}} L \).

We demonstrate the decomposition of the isolevel set \( \mathcal{P}_L(\mu) \) into connected components from the viewpoint of their cardinality. First, we consider the case \( m_i = 1 \) for all \( i \in \mathcal{I} \). Then, by (5.41) one has \( |\mathcal{P}_L(\mu)| = \det F \). Actually this is a consequence of \( \mathcal{P}_L(\mu) \simeq \mathcal{J}_L(\mu) \) and (5.19). In this case, \( \mathcal{P}_L(\mu) \) itself is a connected graph. Next we consider the general cases with \( m_i \geq 1 \). Let \( m, p \) be a pair of positive integers and \( \gamma \) any common divisor of \( m \) and \( p \). We define

\[
C_\gamma(m, p) = \sum_\beta \mu\left( \frac{\beta}{\gamma} \right) \left( \frac{p + m - 1}{p - 1} \right) \tag{5.43}
\]

where \( \beta \) runs over all the common divisors of \( m \) and \( p \) that is a multiple of \( \gamma \). Here, \( \mu \) is the Möbius function in the number theory defined by

\[
\mu(k) = \begin{cases} 
1 & \text{if } k = 1, \\
(-1)^j & \text{if } k \text{ is the product of } j \text{ distinct primes}, \\
0 & \text{otherwise}. 
\end{cases} \tag{5.44}
\]

(This \( \mu \) should not be confused with the Young diagram.) By the Möbius inversion formula, we have

\[
\left( \frac{p + m - 1}{m - 1} \right) = \sum_\gamma C_\gamma(m, p), \tag{5.45}
\]

where \( \gamma \) runs over all the common divisors of \( m \) and \( p \). By (5.41) and (5.45), we obtain

\[
|\mathcal{P}_L(\mu)| = \sum_\gamma \text{mult}(\gamma) \det F_\gamma, \tag{5.46}
\]

\[
\text{mult}(\gamma) = \prod_{i \in \mathcal{I}} \gamma_{i_1}^{C_\gamma(m_i, p_i)} \frac{m_i}{m_i}, \tag{5.47}
\]

where the numbers \( \gamma_{i_1}/m_i, C_\gamma(m_i, p_i) \) turn out to be integers as a result of certain cyclic group actions [69]. This formula is a consequence of the following fact.

**Proposition 5.20** [69]. The \( \text{mult}(\gamma) \) in (5.47) is the multiplicity of the tori in \( \mathcal{P}_L(\mu) \). That is, the following relation is satisfied:

\[
\mathcal{P}_L(\mu) \simeq \bigsqcup_\gamma \text{mult}(\gamma) \left( \mathbb{Z}^g/F_\gamma \mathbb{Z}^g \right). 
\]
Example 5.21. Take \( P_{24}(\mu) \) with
\[
\mu = \begin{pmatrix} \\
1 & 1 & 1 \\
0 & 0 & 1 \\
0 & 0 & 0 \\
\end{pmatrix}
\]
(5.48)

Then, we have \((m_1, m_2, m_3) = (3, 2, 1)\) and \((p_1, p_2, p_3) = (12, 6, 4)\). The matrix \( F \) is given by
\[
F = \begin{pmatrix} 18 & 4 & 2 \\
6 & 14 & 2 \\
6 & 8 & 10 \\
\end{pmatrix}
\]
(5.49)

Possible internal symmetries are \( \gamma = (1, 1, 1), (1, 2, 1), (3, 1, 1) \) and \((3, 2, 1)\). By using (5.43) and (5.47), one has
\[
P_{24}(\mu) \simeq 90 (\mathbb{Z}^3 / F_{(1,1,1)} \mathbb{Z}^3) \sqcup 30 (\mathbb{Z}^3 / F_{(1,2,1)} \mathbb{Z}^3) \sqcup 3 (\mathbb{Z}^3 / F_{(3,1,1)} \mathbb{Z}^3) \sqcup (\mathbb{Z}^3 / F_{(3,2,1)} \mathbb{Z}^3).
\]
(5.50)

The configuration \( \mu \) is common to that in example 5.15. Hence, we can deduce that \( \Sigma(p) \simeq (\mathbb{Z}^3 / F_{(3,1,1)} \mathbb{Z}^3) \) for \( p = 12112211121221122121111 \).

6. Approach by tropical geometry

6.1. Preliminary of tropical geometry

Tropical geometry is the algebraic geometry of the min–plus algebra \((\mathbb{T}, \min, +)\). We introduce the basic notion of the theory of tropical curves, following [58].

6.1.1. Tropical curve.

A tropical polynomial \( F(X) \) of one variable \( X \) is written as
\[
F(X) = \min_{i \in I} (n_i X + C_i) \quad n_i \in \mathbb{Z}_{\geq 0}, C_i \in \mathbb{R},
\]
where \( I \) is a finite subset of \( \mathbb{Z} \). One can regard \( F(X) \) as the tropicalization of a polynomial \( f(x) = \sum_{i \in I} c_i x^{n_i} \in \mathbb{R}_{\geq 0}[x] \) with the transformation \( c_i = e^{-\frac{C_i}{n_i}} \) and \( x = e^{-\frac{1}{x}} \). In the same manner, a tropical polynomial \( F(X, Y) \) of two variables \( X \) and \( Y \) is written as
\[
F(X, Y) = \min_{i \in I} (n_i X + m_i Y + C_i) \quad n_i, m_i \in \mathbb{Z}_{\geq 0}, C_i \in \mathbb{R}.
\]

Very roughly speaking, a tropical curve is a finite graph (i.e. a graph with a finite number of vertices and edges) with a metric structure. In the following, we only consider affine tropical curves in \( \mathbb{R}^2 \) given by a tropical polynomial of two variables. Fix a finite set \( I \) and a tropical polynomial \( F(X, Y) \) of two variables. The tropical curve \( \Gamma \) given by \( F(X, Y) \) is defined as
\[
\Gamma = \{(X, Y) \in \mathbb{R}^2 | F(X, Y) \text{ is indifferentiable}\}.
\]

Example 6.1. See figure 1 for examples of tropical curves, where (a) is a ‘tropical line’ given by \( F(X, Y) = \min(X, Y, 1) \) and (b) is a ‘tropical elliptic curve’ given by \( F(X, Y) = \min(2Y + 7, 2Y + X + 4, Y + 2X, Y + 2X, Y + X + 2, Y + 6, X + 3, 8) \).

The meaning of ‘indifferentiable’ is seen at (a) as follows: Let \( A_1, A_2 \) and \( A_3 \) be three open domains divided by the tropical line. We write \( l_{12}, l_{23} \) and \( l_{13} \) for the three boundaries, and \( P \) for their intersection point \( l_{12} \cap l_{23} \cap l_{13} \). The function \( F(X, Y) = \min(X, Y, 1) \) is ‘differentiable’ at \( (X, Y) \in A_1 \cup A_2 \cup A_3 \), namely we have \( F(X, Y) = 1 \) in \( A_1, F(X, Y) = Y \) in
A_2 and \( F(X, Y) = X \) in \( A_3 \). The function \( F(X, Y) \) is ‘indifferentiable’ at \( (X, Y) \in l_{12} \cup l_{23} \cup l_{13} \) where at least two of \( X, Y \) and 1 become the minimum. For instance, \( F(X, Y) = Y = 1 \) on \( l_{12} \setminus \{P\}, X = Y = 1 \) on \( l_{23} \setminus \{P\}, \) and \( F(X, Y) = X = Y = 1 \) at \( P \).

The edges in tropical curves have rational slopes, and we associate each vertex with a primitive tangent vector which is a tangent vector given by a pair of coprime integers. (If one of the integers is zero, then let another be \( \pm \) 1.) The primitive tangent vector is uniquely determined up to sign. For two vectors \( \xi = (n_1, n_2) \) and \( \xi' = (n'_1, n'_2) \), we set \( \xi \wedge \xi' = n_1n'_2 - n_2n'_1 \).

The following are the definitions of a smooth tropical curve and its genus.

**Definition 6.2.** The tropical curve \( \Gamma_1 \subset \mathbb{R}^2 \) is smooth if the following two conditions hold:

(i) all vertices in \( \Gamma_1 \) are 3-valent.

(ii) For each 3-valent vertex \( v \), let \( \xi_1, \xi_2, \xi_3 \) be the primitive tangent vectors which are outgoing from \( v \). Then, these vectors satisfy \( \xi_1 + \xi_2 + \xi_3 = (0, 0) \) and \( |\xi_i \wedge \xi_j| = 1 \) for \( i, j \in \{1, 2, 3\}, i \neq j \).

When a tropical curve \( \Gamma \) is smooth, the genus of \( \Gamma \) is \( \dim H_1(\Gamma, \mathbb{Z}) \).

A smooth tropical curve is equipped with the metric structure as follows.

**Definition 6.3.** Assume \( \Gamma \) is a smooth tropical curve. Let \( E(\Gamma) \) be the set of edges in \( \Gamma \), and let \( \xi_e \) be the primitive tangent vector of \( e \in E(\Gamma) \). We define the length of edges \( l : E(\Gamma) \rightarrow \mathbb{R}_{\geq 0} \) by

\[
e \mapsto l(e) = \frac{\| e \|}{\| \xi_e \|},\]

where \( \| \| \) is any norm in \( \mathbb{R}^2 \).

**Example 6.4.** Both of the two tropical curves in figure 1 are smooth. For instance, in (b), the 3-valent vertex \( A \) has outgoing primitive tangent vectors \((1, 0), (0, 1) \) and \((-1, -1) \), and the conditions (i) and (ii) in definition 6.2 are satisfied. The genera of the curves (a) and (b) are respectively 0 and 1. The lengths of the edges are \( l(AB) = l(BC) = 1 \) in (b), for example.

We omit the metric structure for non-smooth tropical curves for simplicity. See [58].
6.1.2. Abelian integral and tropical Jacobian variety. Let $\Gamma$ be a smooth tropical curve whose genus $g$ is not zero. We fix $g$ generators $B_1, \ldots, B_g$ of the fundamental group of $\Gamma$ (i.e. generators of the cycles in $\Gamma$).

To describe the abelian integral on $\Gamma$, we need some preparations: for each $e \in E(\Gamma)$, we fix a linear map $\alpha_e : e \to [0, 1]$ (where we have only two choices). For $p_1, p_2 \in e$, we define a fundamental path $p$ by $p = (e; p_1, p_2) \in E(\Gamma) \times \Gamma \times \Gamma$. For a fundamental path $p = (e; p_1, p_2)$, we define $[p_1, p_2; \alpha_e] \subset [0, 1]$ by

$$[p_1, p_2; \alpha_e] = \begin{cases} [\alpha_e(p_1), \alpha_e(p_2)] & \text{if } \alpha_e(p_1) \leq \alpha_e(p_2) \\ [\alpha_e(p_2), \alpha_e(p_1)] & \text{if } \alpha_e(p_1) > \alpha_e(p_2). \end{cases}$$

For two fundamental paths $p = (e; p_1, p_2)$ and $p' = (e'; p'_1, p'_2)$, we define the addition rule only when $e = e'$ and $p_2 = p'_1$ or $p_1 = p'_2$, by

$$p + p' = \begin{cases} (e; p_1, p'_2) & \text{if } p_2 = p'_1 \\ (e; p'_1, p_2) & \text{if } p_1 = p'_2. \end{cases}$$

We define a set of paths $\mathcal{P}$ on $\Gamma$ by

$$\mathcal{P} = \bigoplus_{\text{fundamental path}} \mathbb{Z}p / \text{the addition rule}.$$ 

Then, $\mathcal{P}$ is an infinite-dimensional vector space. For two fundamental paths $p = (e; p_1, p_2)$ and $p' = (e'; p'_1, p'_2)$, we define

$$\text{sgn}(p, p') = \begin{cases} 0 & \text{if } e \neq e' \\ \text{sgn}[(\alpha_e(p_1) - \alpha_e(p_2))(\alpha_e(p'_1) - \alpha_e(p'_2))] & \text{if } e = e', \end{cases}$$

and define a bilinear form of fundamental paths by

$$\langle \cdot, \cdot \rangle : (p, p') \mapsto \langle p, p' \rangle = \text{sgn}(p, p') \cdot l(p \cap p').$$

This naturally gives the bilinear form $\langle \cdot, \cdot \rangle : \mathcal{P} \times \mathcal{P} \to \mathbb{R}$ on $\mathcal{P}$. Briefly speaking, the bilinear form of two paths $p$ and $p'$ on $\Gamma$ is ‘the length of the common part of $p$ and $p'$ with the sign depending on the directions of the two paths’.

Example 6.5. See figure 2 for the smooth tropical curve $\Gamma$ given by

$$F(X, Y) = \min(2Y, X + 3X, Y + 2X, X + 3 + Y + 4, 11).$$

The genus of $\Gamma$ is 2, and we fix the basis $B_1$ and $B_2$ of the fundamental group of $\Gamma$ as depicted. The bilinear forms of $B_1$ and $B_2$ take the values as

$$\langle B_1, B_1 \rangle = 20, \quad \langle B_1, B_2 \rangle = -7, \quad \langle B_2, B_2 \rangle = 14.$$

Let us demonstrate how to compute $\langle B_1, B_2 \rangle$: the common part of $B_1$ and $B_2$ is the edge $PQ$. We set $\hat{QP} \subset B_1$ and $\hat{PQ} \subset B_2$ which are fundamental paths on $\Gamma$. Then, we have $l(\hat{QP} \cap \hat{PQ}) = 7$ and $\text{sgn}(\hat{QP}, \hat{PQ}) = -1$, and the result follows.

Now we introduce the abelian integral and the tropical Jacobian variety for $\Gamma$:

Definition 6.6. Fix $P_0 \in \Gamma$. The abelian integral $\psi : \Gamma \to \mathbb{R}^g$ is given by

$$P \mapsto \psi(P) = (\langle B_i, \hat{P_0}P \rangle)_{i=1,\ldots,g},$$

where we choose a path $\hat{P_0}P$ from $P_0$ to $P$. The map $\psi$ induces the map from a set of divisors $\text{Div}(\Gamma)$ on $\Gamma$ to $\mathbb{R}^g$:

$$\sum_{i \in I} n_i P_i \mapsto \sum_{i \in I} n_i \psi(P_i),$$

where $I$ is a finite set and $n_i \in \mathbb{Z}$. 

54
Definition 6.7. The period matrix $\Xi$ of $\Gamma$ is given by
\[
\Xi = (\langle B_i, B_j \rangle)_{i,j=1,\ldots,g} \in M_g(\mathbb{R}).
\] (6.3)
The tropical Jacobian variety $J(\Gamma)$ of $\Gamma$ is the $g$-dimensional real torus given by
\[
J(\Gamma) = \mathbb{R}^g / \Xi \mathbb{Z}^g.
\] (6.4)

Remark 6.8. The matrix $\Xi$ is symmetric and positive definite by definition, and $J(\Gamma)$ is a tropical analog of Jacobian variety. By removing all infinite edges of $\Gamma$, we obtain the maximal compact subgraph $\Gamma_{\text{cpt}}$ of $\Gamma$. Though the map $\psi$ depends on a choice of the path $P_0 \rightarrow P$, the induced map $\Gamma_{\text{cpt}} \rightarrow J(\Gamma)$ does not depend on the choice and becomes injective. When $g = 1$, $\psi$ induces the isomorphism from $\Gamma_{\text{cpt}}$ to $J(\Gamma)$.

Example 6.9. The tropical curve of genus 1 depicted in figure 1(b) has the period matrix $\Xi = 9$, and the Jacobian variety $\mathbb{R} / 9 \mathbb{Z}$. As for the tropical curve of genus 2 depicted in figure 2, the period matrix and the Jacobian variety are respectively obtained as
\[
\Xi = \begin{pmatrix} 20 & -7 \\ -7 & 14 \end{pmatrix}, \quad J(\Gamma) = \mathbb{R}^2 / \Xi \mathbb{Z}^2.
\]

6.1.3. Tropical Riemann theta function. Fix a positive integer $g$ and a symmetric and positive definite matrix $\Xi \in M_g(\mathbb{R})$. (Here, the matrix $\Xi$ is not always a period matrix of some tropical curve.)

Definition 6.10. The tropical Riemann theta function $\Theta(Z; \Xi)$ of $Z \in \mathbb{R}^g$ is defined by
\[
\Theta(Z; \Xi) = \min_{n \in \mathbb{Z}^g} \left\{ n \cdot \left( \frac{1}{2} \Xi n + Z \right) \right\}.
\]
We call the $g$-dimensional real torus given by
\[
J_\Xi = \mathbb{R}^g / \Xi \mathbb{Z}^g
\] (6.5)
the principally polarized tropical abelian variety. (If $\Xi$ is the period matrix of a tropical curve $\Gamma$, then $J_\Xi$ is nothing but the tropical Jacobian variety $J(\Gamma)$.)
It is easy to see the following:

**Lemma 6.11.** The function $\Theta(Z) = \Theta(Z; \Xi)$ satisfies the quasi-periodicity:

$$
\Theta(Z + \Xi \mathbf{m}) = -\mathbf{m} \cdot \left( \frac{1}{2} \Xi \mathbf{m} + Z \right) + \Theta(Z) \quad \mathbf{m} \in \mathbb{Z}^g.
$$

**Remark 6.12.** Recall the Riemann’s theta function:

$$
\theta(z; K) = \sum_{\mathbf{n} \in \mathbb{Z}^g} \exp(\pi i \mathbf{n} \cdot (K \mathbf{n} + 2z)) \quad z \in \mathbb{C}^g,
$$

where $K \in M_g(\mathbb{C})$ is symmetric and $\text{Im}K$ is positive definite. The function $\theta(z; K)$ satisfies the periodicity and quasi-periodicity:

$$
\theta(z + \mathbf{m}; K) = \theta(z; K),
$$

$$
\theta(z + K \mathbf{m}; K) = \exp(-\pi i \mathbf{m} \cdot (K \mathbf{m} + 2z)) \theta(z; K)
$$

for $\mathbf{m} \in \mathbb{Z}^g$. Remark that only the quasi-periodicity remains in the tropical case.

### 6.2. General solution for the tropical periodic Toda lattice

We briefly present the results on the general solution for the tropicalization of the $N$-periodic Toda lattice (trop-pToda) following [29]. This section offers not only an application of the tropical geometry but also a preparation for the next section where we study the periodic BBS Toda lattice (trop-pToda) following [29]. This section offers not only an application of the tropical Toda lattice, where ‘ultradiscrete’ means ‘tropical’ in our present terminology, hence the naming ‘trop-p-Toda’ here.)

**Proposition 6.13 [41, proposition 2.1].** Equation (6.9) is obtained as the tropicalization of the discrete Toda lattice (4.18) and (4.19) with a periodic boundary condition $q_{j+N}^t = q_j^t$, $w_{j+N}^t = w_j^t$ and the condition $\prod_{j=1}^N w_j^t/q_j^t < 1$ so that the tropicalization of $(1 - \prod_{j=1}^N w_j^t/q_j^t)$ is zero.

**Proof.** First we show that under $N$-periodic boundary condition, (4.18) and (4.19) are expressed as

$$
q_{j+1}^t = q_j^t + q_j^t \frac{1 - \prod_{j=1}^N (w_j^t/q_j^t)}{\sum_{j=0}^{N-1} \prod_{i=1}^k (w_j^t/q_j^t)}.
$$

(6.10)

With a common denominator, the rhs of (6.10) is rewritten as

$$
q_{j+1}^t = q_j^t \frac{\sum_{j=0}^{N-1} \prod_{i=1}^k (w_j^{t+1}/q_j^{t+1})}{\sum_{j=0}^{N-1} \prod_{i=1}^k (w_j^{t+1}/q_j^{t+1})}.
$$

(6.11)

On the other hand, (4.25) are equivalent to (4.18) and (4.19) under the substitution of variables $q_{j+1}^t = 1/x_j$, $w_j^t = 1/y_j$, $q_j^{t+1} = 1/x_j$, $w_j^{t+1} = 1/x_j$. Hence, the birational $R$ given by (4.23)
is also equivalent to the \(N(= n + 1)\)-periodic discrete Toda lattice equation. From (4.23) with the above variable substitution, we obtain

\[
q^{t+1}_j = q^{t}_j \sum_{k=1}^{N} \prod_{
u=k}^{N} (1/q^{t+1}_{j+i+1}) \prod_{i=1}^{k} (1/w^{t}_j)
\]

\[
= q^{t}_j \sum_{k=1}^{N} \prod_{
u=k}^{N} (1/q^{t+1}_{j+i+1}) \prod_{i=0}^{k-1} (1/w^{t+1}_{j+i})
\]

\[
= q^{t}_j \sum_{k=1}^{N} \prod_{
u=k}^{N-1} (1/q^{t+1}_{j+i+1}) \prod_{i=0}^{k-1} (1/w^{t+1}_{j+i})
\]

which becomes (6.11) by the replacements \(k \to N - k\), \(l \to N - l\).

Next we apply tropicalization to (6.10) and (4.19). Since the numerator of the second term in (6.10) is a constant with respect to \(t\), the tropicalization of this numerator is constantly zero under the given condition on \(\prod_{j=1}^{N} w^t_j/q^t_j\). Thus, (6.10) and (4.19) yield (6.9).

The system (6.9) has \(N + 1\) conserved quantities \(H_k(k = 1, \ldots, N + 1)\) given by the tropical polynomials on \(T\) as

\[
H_1 = \min_{1 \leq i, j \leq N} (Q_i, W_j),
\]

\[
H_2 = \min \left( \min_{1 \leq i < j \leq N} (Q_i + Q_j), \min_{1 \leq i, j \leq N} (W_i + W_j), \min_{1 \leq i, j \leq N, j \neq i-1} (Q_i + W_j) \right),
\]

\[
\ldots, \quad H_N = \min \left( \sum_{j=1}^{N} Q_j, \sum_{j=1}^{N} W_j \right),
\]

\[
H_{N+1} = \sum_{j=1}^{N} (Q_j + W_j).
\]

Fix \(C = (C_k)_{k=1,\ldots,N+1} \in \mathbb{R}^{N+1}\) and define the isospectral set \(T_C\) by

\[
T_C = \{ \tau \in T | H_k(\tau) = C_k(k = 1, \ldots, N + 1) \},
\]

and the affine tropical curve \(\Gamma_C\) given by the differentiable points of

\[
F(X, Y) = \min(2Y, Y + \min(NX, (N - 1)X + C_1, \ldots, X + C_{N-1}, C_N), C_{N+1}).
\]

We call \(\Gamma_C\) the spectral curve of the trop-pToda. For the derivation of the conserved quantities (6.13) and \(F(X, Y)\) (6.15), see [29, section 3.1, section 3.2]. We set \(L\) and \(\lambda_k, \eta_k\) for \(k = 0, \ldots, N - 1\) as

\[
L = C_{N+1} - 2(N - 1)C_1,
\]

\[
\lambda_0 = 0, \quad \lambda_k = C_{k+1} - C_k \quad k = 1, \ldots, N - 1,
\]

\[
\eta_0 = L, \quad \eta_k = L - 2 \sum_{j=1}^{N-1} \min(\lambda_k, \lambda_j) \quad k = 1, \ldots, N - 1.
\]

The curve \(\Gamma_C\) is smooth if and only if \(\lambda_1 < \lambda_2 < \cdots < \lambda_{N-1}\) and \(\eta_k > 0\) for \(k = 1, \ldots, N - 1\). The genus of the smooth \(\Gamma_C\) is \(N - 1\). See figure 3 for \(\Gamma_C\), where we set \(C_1 = 0\) for simplicity.

Assume \(\Gamma_C\) is smooth and write \(g\) for the genus, \(g = N - 1\). Fix the basis \(B_1, \ldots, B_g\) of the fundamental group \(\pi_1(\Gamma_C)\) as figure 3. In what follows, we denote by \(\Omega\) the period matrix (6.3) of \(\Gamma_C\). The matrix \(\Omega = (\Omega_{ij})_{i,j=1,\ldots,g}\) is explicitly written as

\[
\Omega_{ij} = \begin{cases} 
\eta_{i-1} + \eta_i + 2(\lambda_j - \lambda_{i-1}) & i = j \\
-\eta_i & j = i + 1 \\
-\eta_j & i = j + 1 \\
0 & \text{otherwise}
\end{cases}
\]

and we get the tropical Jacobian variety of \(\Gamma_C\) as \(J(\Gamma_C) = \mathbb{R}^g/\Omega\mathbb{Z}^g\).

The general solution for the trop-pToda is obtained by the following theorem.
Theorem 6.14. When $\Gamma_C$ is smooth, we have the following.

(i) [30, theorem 3.5] Fix $Z_0 \in \mathbb{R}^g$ and define $T_t^n = \Theta(Z_0 + \lambda t - L e_1 n)$, where

$$\lambda = (\lambda_1, \lambda_2 - \lambda_1, \ldots, \lambda_g - \lambda_{g-1}), \quad e_1 = (1, 0, \ldots, 0) \in \mathbb{R}^g.$$  

The general solution for the trop-pToda is given by

$$Q_t^n = T_{t+1}^n - T_{t-1}^n + T_{t+n}^n + C_1,$$
$$W_t^n = T_{t+1}^n - T_{t-1}^n + L + C_1.$$  

(ii) [31, theorem 1.3] This solution induces the isomorphism $J(\Gamma_C) \cong T_C$. In particular, the time evolution of the trop-pToda is linearized on $J(\Gamma_C)$, whose velocity is $\lambda$.

Example 6.15. The case of $N = 2$. In this simplest case, we can explicitly construct the isomorphism $\alpha$:

$$T_C \xrightarrow{\alpha} \Gamma_C^{\text{cp}} \xrightarrow{\phi} J(\Gamma_C) \xrightarrow{\cong} (B_1, P_0, P).$$  

$$\begin{align*}
T_C & \quad \longrightarrow \quad \Gamma_C^{\text{cp}}_C \\
(Q_1, W_1, Q_2, W_2) & \quad \mapsto \quad P = (\min(Q_2, W_1), Q_1 + W_1) \\
& \quad \mapsto \quad (B_1, P_0, P).
\end{align*}$$
The solution (6.18) induces the inverse map of \( \psi \circ \alpha \). Let us consider the case of \( C = (0, 3, 8) \), where \( \Gamma_C \) is depicted as

The following is an example of linearization, where one sees \( \lambda = (3) \). We set \( P_0 = O \):

\[
T_C = \{(Q_1, W_1, Q_2, W_2)\} \overset{\alpha}{\longrightarrow} \Gamma_C^{\text{cpt}} \overset{\psi}{\longrightarrow} J(\Gamma_C) \simeq \mathbb{R}/16\mathbb{Z}
\]

For general \( N > 2 \), the isomorphism \( T_C \to J(\Gamma_C) \) is regarded as a composition of the injective map \( \alpha : T_C \to \text{Div}_{\text{eff}}(\Gamma_C) \) and the abelian integral \( \psi \), but \( \alpha \) becomes too complicated.

**Example 6.16.** The case of \( N = 3 \) and \( C = (0, 2, 6, 19) \). We have \( \Omega = \left( \begin{array}{cc} 34 & -11 \\ -11 & 22 \end{array} \right) \) and \( \lambda = (2, 2) \). Observe that the velocity in \( J(\Gamma_C) \) is indeed \( \lambda \).

\[
T_C = \{(Q_1, W_1, Q_2, W_2, Q_3)\} \simeq J(\Gamma_C)
\]

**Remark 6.17.** Theorem 6.14 corresponds to a tropical version of [9, 35] where the general solution for the periodic Toda lattice is studied by using (complex) algebraic geometry. When \( \Gamma_C \) is not smooth, neither the structure of \( T_C \) nor the solution has been clarified yet. It requires a further study on a degeneration of the period matrix \( \Omega \) and Jacobian variety \( J(\Gamma_C) \).

**Remark 6.18.** In [32], \( \lambda_i \)s and \( \Omega \) were derived by directly ultradiscretizing abelian integrals on the spectral curve of the periodic discrete Toda lattice. By combining this strategy and tropical curve theory, theorem 6.14(i) was proved in [30].
6.3. Periodic BBS and tropical geometry

As a periodic version of section 4.2.2, we have an embedding of the states of the periodic BBS in those of the trop-pToda [41, 29]. Differently from the case of the original BBS, this embedding is not always consistent with the time evolution of the trop-pToda. We revisit the results in section 5.2.4 with this embedding and tropical geometry.

Let $\mathcal{P}_L(\mu)$ (5.5) be the isolevel set of the $L$-periodic BBS with the configuration $\mu = (\mu_1, \ldots, \mu_g)$, (Recall that we assumed $i_1 < \cdots < i_g$.) Set $N = 1 + \sum_{k=1}^{g} m_k$ in section 6.2, and fix $C = (C_1, \ldots, C_{N+1})$ at (6.14) as $C_1 = 0$, $C_{N+1} = L$.

\[ C_{m_i + \cdots + m_{i-1} + k + 1} = \sum_{j=1}^{k-1} i_j m_j + ii l, \quad k = 1, \ldots, g, \quad l = 1, \ldots, m_i. \tag{6.19} \]

Then, the embedding $\eta : \mathcal{P}_L(\mu) \rightarrow \mathcal{T}_C$ is defined as follows: among $L$ boxes, fix 'the leftmost box' (it can be any box) and do the following procedure.

(i) If the leftmost box is occupied, then set $Q_1 =$ (the number of the first consecutive balls from the left), otherwise set $Q_1 = 0$.

(ii) Set $W_i =$ (the number of $i$th consecutive empty boxes from the left) for $i = 1, \ldots, N$. If $Q_1 \neq 0$, set $Q_i =$ (the number of the $i$th consecutive balls from the left), otherwise set $Q_i =$ (the number of the $(i-1)$th consecutive balls from the left) for $i = 2, \ldots, N$.

Then, we obtain

\[
\begin{array}{cccccccc}
W_1 & Q_2 & W_2 & W_{N-1} & Q_{N} & W_{N} \\
\hline
1 \ldots 1 \ldots 2 \ldots 2 \ldots 1 \ldots 1 \ldots \ldots 1 \ldots 1 \\
\end{array}
\]

when $Q_1 = 0$.

\[
\begin{array}{cccccccc}
Q_1 & W_i & Q_i & W_i \\
\hline
2 \ldots 2 \ldots 1 \ldots 2 \ldots 2 \ldots 1 \ldots 1 \ldots \ldots 2 \ldots 2 \\
\end{array}
\]

when $Q_1 > 0$.

Note that we have $Q_1 = 0$ or $W_N = 0$.

**Example 6.19.** The case of $L = 9$, $\mu = (3, 1)$ and $N = 3$. We have $C = (0, 1, 4, 9)$. The evolution of the periodic BBS in $\mathcal{P}_L(\mu)$ is at the left, and its embedding in $\mathcal{T}_C = [(Q_1, W_1, Q_2, W_2, Q_3, W_3)]$ is in the center. The evolution of the trop-pToda in $\mathcal{T}_C$ is written at the right.

\[
\begin{array}{ccc}
t=0 & 1222112121 & (0, 1, 3, 2, 1, 2) \\
t=1 & 1112221222 & (0, 4, 2, 1, 2, 0) \\
t=2 & 2221112121 & (3, 3, 1, 2, 0, 0) \\
t=3 & 1122112121 & (3, 3, 1, 2, 0, 0) \\
\end{array}
\]

The time evolution does not agree with the embedding at $t = 3$.

Let $T_\infty$ and $T_{\text{toda}}$ be the time evolution operators in $\mathcal{P}_L(\mu)$ and $\mathcal{T}_C$, respectively. As one observes in the above example, in general the following diagram is not commutative:

\[
\begin{array}{ccc}
\mathcal{P}_L(\mu) & \xrightarrow{\eta} & \mathcal{T}_C \\
\downarrow T_\infty & & \downarrow T_{\text{toda}} \\
\mathcal{P}_L(\mu) & \xrightarrow{\eta} & \mathcal{T}_C \\
\end{array}
\]

i.e. $\eta \circ T_\infty \neq T_{\text{toda}} \circ \eta$.

**Proposition 6.20** [29, proposition 4.4]. Let $s$ be a shift operator on $\mathcal{T}_C$ given by

\[
s : (Q_1, W_1, Q_2, W_2, \ldots, Q_N, W_N) \mapsto (Q_2, W_2, \ldots, Q_N, W_N, Q_1, W_1).
\]
We write $\mathcal{T}_C/\sim_c$ for the quotient space of $\mathcal{T}_C$ with respect to the action of $s$. Then, the following diagram is commutative:

\[
\begin{align*}
\mathcal{P}_L(\mu) & \xrightarrow{\eta^*} \mathcal{T}_C/\sim_c \\
\downarrow \tau_{\infty} & \downarrow \tau_{\text{ratio}} \\
\mathcal{P}_L(\mu) & \xrightarrow{\eta^*} \mathcal{T}_C/\sim_c
\end{align*}
\]

(6.20)

The induced map $\eta^*$ gives one-to-one correspondence between $\mathcal{P}_L(\mu)$ and $(\mathcal{T}_C \cap \mathbb{Z}^{2n})/\sim_c$.

In example 6.19, we have $s : (3, 1, 1, 1, 0, 3) \mapsto (0, 3, 3, 1, 1, 1)$ at $t = 3$, which indicates the commutativity of the diagram (6.20).

Now we come to the final stage of this section. Set $m_k = 1 (k = 1, \ldots, g)$, thus (6.19) gives (6.16) with $\lambda_k = i_k$ and $\eta_k = p_{i_k}$ (5.8). Then, the spectral curve $\Gamma_C$ is smooth, and the isolevel set $\mathcal{T}_C$ is isomorphic with $J(\Gamma_C)$ (theorem 6.14). On the other hand, we have the important result on the periodic BBS, the one-to-one correspondence between $\mathcal{P}_L(\mu)$ and $J_L(\mu)$ due to the map $\Phi$ (theorems 5.8, 5.10). These results and proposition 6.20 are summarized as follows, which gives a tropical geometrical explanation for $J_L(\mu)$:

**Proposition 6.21.**

(i) [29, lemma 2.5] We keep the setting of $J(\Gamma_C)$ and $J_L(\mu)$. Let $J_F = \mathbb{R}^g/F\mathbb{Z}^g$ be the principally polarized tropical abelian variety where the matrix $F$ is defined by (5.19). Let $c$ be a shift operator on $J(\Gamma_C)$ given by

\[c : [(Z_1, Z_2, \ldots, Z_g)] \mapsto [(Z_1 + L, Z_2, \ldots, Z_g)].\]

Then, we have $J_F \cong J(\Gamma_C)/\sim_c$, where $J(\Gamma_C)/\sim_c$ is the quotient space of $J(\Gamma_C)$ with respect to $c$.

(ii) [29, equation (4.5)] We have the following commutative diagram:

\[
\begin{align*}
\mathcal{P}_L(\mu) & \xrightarrow{\eta^*} \mathcal{T}_C/\sim_c \quad \Leftarrow \quad \mathcal{T}_C \\
\Phi \downarrow \text{iso.} & \downarrow \text{iso.} \\
J_L(\mu) & \subset J_F \cong J(\Gamma_C)/\sim_c \quad \Leftarrow \quad J(\Gamma_C)
\end{align*}
\]

**Example 6.22.** We illustrate proposition 6.21 (i) by using example 6.19. The period matrices $\Omega$ (6.17) and $F$ (5.19) of $J(\Gamma_C)$ and $J_F$ are, respectively,

\[
\Omega = \begin{pmatrix}
16 & -5 \\
-5 & 10
\end{pmatrix}, \quad F = \begin{pmatrix}
7 & 2 \\
2 & 7
\end{pmatrix}.
\]

By changing the basis of $\pi_1(\Gamma_C)$ from $B_1, B_2$ to $B_1, B_1 + B_2$, the period matrix $\Omega$ is transformed into

\[
\Omega' = \begin{pmatrix}
1 & 0 \\
1 & 1
\end{pmatrix} \Omega \begin{pmatrix}
1 & 1 \\
0 & 1
\end{pmatrix} = \begin{pmatrix}
16 & 11 \\
11 & 16
\end{pmatrix}.
\]

(Of course we have $J_{Q_1} \cong J_{Q_2}$.) The shift operator $c$ acts on $J_{Q_1}$ as $c : [(Z_1, Z_2)] \mapsto [(Z_1 + 9, Z_2 + 9)]$, and we have $\mathbb{R}^2/F\mathbb{Z}^2 \cong J_{Q_1}/\sim_c$. This indicates $J_F \cong J(\Gamma_C)/\sim_c$.
