HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Abstract

We investigate the relationship between ergodicity and asymptotic Gaussianity of isotropic spherical random fields, in the high-resolution (or high-frequency) limit. In particular, our results suggest that under a wide variety of circumstances the two conditions are equivalent, i.e. the sample angular power spectrum may converge to the population value if and only if the underlying field is asymptotically Gaussian, in the high frequency sense. These findings may shed some light on the role of Cosmic Variance in Cosmic Microwave Background (CMB) radiation data analysis.

Keywords and Phrases: Spherical Random Fields, High-Frequency Gaussianity, High-Frequency Ergodicity, Gaussian Subordination, Clebsch-Gordan Coefficients, Cosmic Variance

PACS: 02.50-r, 98.70-Vc, 98.80-k

AMS Classification: 60G60; 60G15, 60K40, 62M15, 42C10

1 Introduction and background

1.1 Overview

The usual framework for proving asymptotic results in probability (for instance, central limit theorems or laws of large numbers) lies within the so-called large sample paradigm, according to which more and more (independent or weakly dependent) random variables are generated, and the limiting behaviour of some functionals of these variables (e.g., averages or empirical moments) is studied.

Physical applications, however, are prompting the development of a stochastic asymptotic theory of a rather different nature, where the indefinite repetition of a single experience is no longer available, and one relies instead on observations of the same (fixed) phenomenon with higher and higher degrees of resolution.

One crucial instance of this situation appears when dealing with the statistical analysis of random fields indexed by compact manifolds, the quintessential example being provided by the case of the sphere $S^2$. Indeed, we are especially concerned with issues arising from the analysis of the Cosmic Microwave Background (CMB) radiation, a theme which is currently at the core of physical and cosmological research, see for instance [12, 20] for textbook references, and [38, 39, 21] for further discussions around the latest experimental data.

*We are grateful to Mirko D’Ovidio for some useful comments on an earlier version.
It is well-known that the CMB is a relic electromagnetic radiation providing a snapshot of the Universe at the so-called \textit{age of recombination}, i.e. at the era when electrons in the primordial fluid arising from the Big Bang were captured by protons to form stable hydrogen atoms. Since the cross-section of hydrogen atoms is much smaller than for free electrons, after recombination photons can be viewed as diffusing freely across the Universe (to first order approximations). According to the latest experimental evidence, this has occurred some $3.7 \times 10^5$ years after the Big Bang, i.e. 13.7 billion years from the current epoch. Several experiments have been devoted to collecting extremely refined observations of the CMB, the leading role being played by the currently ongoing NASA mission WMAP (launched in 2001, see http://map.gsfc.nasa.gov/) and the ESA mission Planck, which is just now starting to operate after the launch on May 14, 2009 (see http://www.sciops.esa.int/).

From a mathematical point of view, the CMB can be regarded as a single realization of an isotropic, zero-mean, finite variance spherical random field, for which the following spectral representation holds (see e.g. [1] or [22])

$$T(x) = \sum_{l=0}^{\infty} \sum_{m=-l}^{l} a_{lm} Y_{lm}(x), \quad x \in S^2. \quad (1)$$

Here, the collection

$$\{ Y_{lm} : l \geq 0, \ m = -l, \ldots, l \}$$

stands for the usual triangular array of spherical harmonics, which are well-known to provide a complete orthonormal system for the $L^2(S^2)$ space of square-integrable functions (with respect to Lebesgue measure) on the sphere – see [40, 43, 44]. In a loose sense, we can say that the frequency parameter $l$ is related to a characteristic angular scale, say $\vartheta_l$, according to the relationship $\vartheta_l \simeq \pi/l$. The (random) triangular array of spherical harmonic coefficients $\{a_{lm} : l \geq 0, \ m = -l, \ldots, l \}$ are such that $Ea_{lm} = 0$ and $Ea_{lm} \overline{a}_{lm'} = C_l \delta^{ll'} \delta_{mm'}$, the bar denoting complex-conjugation and $\delta_{ab}$ indicating the Kronecker delta function. The non-negative sequence $\{C_l : l \geq 0 \}$ (not depending on $m$ – see [29] as well as the forthcoming section) is the angular power spectrum of the spherical field (see for instance [2, 3]).

As recalled above, our work deals with asymptotic issues, where the expression “asymptotic” has to be understood in the \textit{high-resolution} (or \textit{high-frequency}) sense. This means that we focus on the behaviour of the Fourier components

$$T_l(x) := \sum_{m=-l}^{l} a_{lm} Y_{lm}(x), \quad x \in S^2, \ l \geq 0, \quad (2)$$

associated with a fixed spherical field, as the frequency $l$ grows larger and larger (plainly, each $T_l$ is the projection of the field $T$ into the orthogonal subspace of $L^2(S^2)$ spanned by the spherical harmonics $\{ Y_{lm} : m = -l, \ldots, l \}$). Note that this is the typical framework faced by experimentalists handling satellite missions as those mentioned above. Indeed, these missions are observing the same (unique) realization of our Universe on the so-called \textit{last scattering surface}; more recent and more sophisticated experiments are then characterized by higher and higher frequencies (smaller and smaller scales) being observed. For instance, for the pioneering CMB mission COBE in 1989-1992 (which led to the Nobel Prize for Smoot and Mather in 2006) only frequencies in the order of a few dozens were recorded (i.e., scales of several degrees), a
limit which was raised to few hundreds by WMAP (i.e., approximately a quarter of degree) and is expected to grow to a few thousands with Planck (i.e., a few arcminutes).

The principal goal of this paper is to enlighten some partial new connections between two high-resolution characterizations of spherical fields, that is, ergodicity and asymptotic Gaussianity. Roughly speaking (formal details are given in the forthcoming Sections 1.2 and 1.3), one says that the spherical field \( T \) is ergodic if the empirical version of the power spectrum of \( T \) (see formula (3) below) can be used as a consistent estimator of the sequence \( \{C_l\} \) (at least for high values of \( l \)). On the other hand, we say that \( T \) is asymptotically Gaussian, whenever suitably normalized versions of the frequency components of \( T_l \) exhibit Gaussian fluctuations for high values of \( l \). As discussed below, these two notions are tightly connected whenever one deals with fields having an isotropic (or, equivalently, rotationally-invariant) law.

**Remark.** For the rest of the paper, every random object is defined on a suitable (common) probability space \((\Omega, \mathcal{F}, P)\).

### 1.2 High-frequency ergodicity

In what follows, we shall consider a real-valued random field \( T = \{T(x) : x \in S^2\} \) indexed by the sphere \( S^2 \). The random field \( T \) satisfies the following basic assumptions: (i) the law of \( T \) is isotropic, that is, \( T \) has the same law as \( x \mapsto T(gx) \) for every rotation \( g \in SO(3) \) (here, we select the canonical action of \( SO(3) \) on \( S^2 \)); (ii) \( T \) is square-integrable and centered. Under assumptions (i)-(ii), the harmonic expansion \( \hat{T} \) takes place, both in \( L^2(P) \) (for fixed \( x \)) and in the product space \( L^2(\Omega \times S^2, \mathcal{P} \otimes d\lambda) \), where \( \lambda \) stands for the Lebesgue measure.

Note that the last claim hinges on the fact that one can regard \( T \) as an application of the type \( T : \Omega \times S^2 \rightarrow \mathbb{R} : (\omega, x) \mapsto T(\omega, x) \). As anticipated in the previous section, another useful property of \( T \) (easily deduced from isotropy – see e.g. [29]) is that the harmonic coefficients \( a_{lm} \) are such that the power spectrum associated with \( T \), defined as the collection \( \{C_l : l = 0, 1, ...\} \) (with \( C_l = E|a_{lm}|^2 \)), depends uniquely on the frequency indices \( l \).

In physical experiments (for instance, when measuring the CMB radiation), the power spectrum of a given spherical field is usually unknown. For this reason, a key role is played by its empirical counterpart (called the empirical power spectrum – see for instance [34],[63]), which is given by

\[
\hat{C}_l = \frac{1}{2l+1} \sum_{m=-l}^{l} |a_{lm}|^2 , \quad l = 0, 1, 2, ...
\]

(3)

An important issue to be addressed is therefore to establish conditions under which the distance between the quantities \( \hat{C}_l \) and \( C_l \) converges to zero (in a sense that is defined below) when \( l \to \infty \), that is, when higher and higher frequencies of the expansion \( \hat{T} \) are available to the observer. Although the asymptotic behaviour of spectrum estimators has been very deeply investigated for stochastic processes in Euclidean domains and under large sample asymptotics (see for instance [3],[23],[63]), only basic results are known in the high-resolution setting.

For instance, it is immediate that the finite variance of \( T \) entails that, for every \( x \in S^2 \),

\[
ET(x)^2 = \sum_{l \geq 0} \frac{(2l+1)}{4\pi} C_l < \infty,
\]
from which one deduces that $C_l \rightarrow 0$ and also

$$\sum_{l \geq 0} E\hat{C}_l = \sum_{l \geq 0} C_l < \infty.$$ 

By reasoning as in the proof of the Borel-Cantelli Lemma we therefore infer that, for any $\varepsilon > 0$,

$$P\left\{ \lim_{l \rightarrow \infty} \sup \hat{C}_l > \varepsilon \right\} \leq \lim_{l \rightarrow \infty} \sum_{l \geq l} P\left\{ \hat{C}_l \geq \varepsilon \right\} \leq \lim_{l \rightarrow \infty} \frac{1}{\varepsilon} \sum_{l \geq l} C_l = 0,$$

yielding in turn that both $\hat{C}_l$ and $|\hat{C}_l - C_l|$ almost surely converge to zero as $l \rightarrow \infty$. Plainly, since this result does not provide any information about the magnitude of the ratio $|\hat{C}_l - C_l|/C_l$, it is virtually useless for statistical applications. In particular, one cannot conclude from (4) that the estimation of $C_l$ based on $\hat{C}_l$ is consistent in a satisfactory statistical sense.

Starting from these considerations, one sees that it is indeed necessary to focus on normalized quantities, such as the sequence

$$\tilde{C}_l = \frac{1}{2l + 1} \sum_{m=-l}^{l} |a_{lm}|^2 \hat{C}_l / C_l, \quad l \geq 0. \tag{5}$$

Note that $E\tilde{C}_l = 1$, and also that the coefficient $\tilde{C}_l$ is not observable (whereas $\hat{C}_l$ is). The sequence $\{\tilde{C}_l : l \geq 0\}$ can be used in order to meaningfully evaluate the asymptotic performance of any statistical procedure based on $\tilde{C}_l$. The following definition uses the coefficients $\tilde{C}_l$ in order to define ergodicity.

**Definition 1 (HFE)** Let $T$ be an isotropic, finite variance spherical random field with angular power spectrum $\{C_l : l \geq 0\}$. We shall say that $T$ is **High-Frequency Ergodic** (HFE – or ergodic in the high-frequency sense) if and only if

$$\lim_{l \rightarrow \infty} E\{\tilde{C}_l - 1\}^2 = \lim_{l \rightarrow \infty} E\left\{ \frac{\hat{C}_l}{C_l} - 1 \right\}^2 = 0. \tag{6}$$

Condition (6) implies of course that $\tilde{C}_l = \hat{C}_l / C_l$ converges in probability towards the constant 1.

**Remark.** In some sense, the term “high-frequency consistency” seems to better describe property (6). However, in the statistical literature consistency is usually viewed as a property of a sequence of estimators, whereas here we deal with a property of the field $T$, so that we find the term ergodicity more suitable. Another way of formulating this point is to say that (6) characterizes the ergodicity of the “normalized empirical spectral measure” $\{\hat{C}_l : l \geq 0\}$, as $l$ diverges.

### 1.3 Ergodicity of Gaussian fields (and associated Gaussian fluctuations)

As an illustration (and for future reference) we now test Definition (6) under the additional assumption that $T$ is Gaussian. In this case, it is readily seen that, for every $l \geq 1$, the components
of the vector \( \{a_{lm} : m = 1, \ldots, l\} \) are complex-valued and independent. Moreover, the random quantities \( a_{l0}/\sqrt{C_l}, \sqrt{2}\text{Re}(a_{lm})/\sqrt{C_l} \) and \( \sqrt{2}\text{Im}(a_{lm})/\sqrt{C_l} \) (\( m = 0, \ldots, l \)) are independent and identically distributed \( N(0, 1) \) random variables (these facts are well-known, see e.g. [2, 29] and the references therein). It is now easy to prove that

\[
\tilde{C}_l = \frac{1}{2l + 1} \sum_{m=-l}^{l} \frac{|a_{lm}|^2}{C_l} \to 1, \tag{7}
\]

in every norm \( L^p, \ p \geq 1 \). Indeed, since \( a_{l0}/\sqrt{C_l} \sim \chi^2_1 \) and the set \( \{2a_{lm}^2/C_l : m = 1, \ldots, l\} \) is composed of i.i.d. \( \chi^2_2 \) random variables independent of \( a_{l0} \) (here, \( \chi^2_n \) denotes a standard chi-square distribution with \( n \) degrees of freedom),

\[
E \left\{ (\tilde{C}_l - 1)^2 \right\} = \frac{1}{(2l + 1)^2} E \left[ \frac{a_{l0}^2}{C_l} - 1 + 2 \left( \sum_{m=1}^{l} \frac{|a_{lm}|^2}{C_l} - 1 \right) \right]^2
= \frac{2}{2l + 1} \to 0,
\]

and one can use the fact that, for polynomial functionals of a Gaussian field of fixed degree, all \( L^p \) topologies coincide.

We shall now provide (see the forthcoming Proposition 2) a CLT that is naturally associated with the convergence described in (7). Note that, instead of using the classic Berry-Esseen results (see e.g. Feller [15]), we rather apply some recent estimates (proved in [32] and [33] by means of infinite-dimensional Gaussian analysis and the so-called “Stein’s method” for probabilistic approximations) allowing to compare, for fixed \( l \), the total variation distance between the law of the normalized random variable

\[
\sqrt{\frac{2l + 1}{2}} \left\{ \tilde{C}_l / C_l - 1 \right\} \to \sqrt{\frac{8}{2l + 1}} \cdot \left\{ \tilde{C}_l - 1 \right\},
\]

and that of a standard Gaussian random variable. Recall that the total variation distance between the laws of two real-valued random variables \( X \) and \( Y \) is given by

\[
d_{TV}(X, Y) = \sup_A |P(X \in A) - P(Y \in A)|,
\]

where the supremum runs over all Borel sets \( A \).

**Proposition 2** Let \( N(0, 1) \) denote a centered standard Gaussian random variable. Then, for all \( l \geq 0 \) we have

\[
d_{TV} \left( \sqrt{\frac{2l + 1}{2}} \left\{ \tilde{C}_l / C_l - 1 \right\}, N(0, 1) \right) \leq \sqrt{\frac{8}{2l + 1}}, \tag{8}
\]

so that, in particular, as \( l \to \infty \),

\[
\sqrt{\frac{2l + 1}{2}} \left\{ \tilde{C}_l - 1 \right\} \xrightarrow{\text{law}} N(0, 1). \tag{9}
\]
Proof. We have
\[
\sqrt{\frac{2l+1}{2}} \left\{ \frac{\hat{C}_l}{C_l} - 1 \right\} = \frac{1}{\sqrt{2(2l+1)}} \left\{ \frac{a_{lm}^2}{C_l} + \sum_{m=1}^{l} \frac{(\text{Re} a_{lm})^2 + (\text{Im} a_{lm})^2}{C_l} - (2l+1) \right\}
\]
\[
= \frac{1}{\sqrt{2(2l+1)}} \left\{ \sum_{m=1}^{2l+1} \frac{(x_{lm}^2 - 1)}{\sqrt{2}} \right\},
\]
where \( \{x_{lm}\} \) are a triangular array of i.i.d. standard Gaussian random variables. Standard calculations yield that
\[
\text{cum}_4 \left\{ \frac{\sqrt{2}}{\sqrt{2(2l+1)}} \left[ \sum_{m=1}^{2l+1} \frac{(x_{lm}^2 - 1)}{2} \right] \right\} = \frac{12}{2l+1},
\]
where \( \text{cum}_j \) stands for the \( j \)th cumulant. Now recall that in [33] it is proved that, for every zero mean and unit variance random variable \( F_q \) that belongs to the \( q \)th Wiener chaos associated with some Gaussian field \( (q \geq 2) \), the following inequality holds:
\[
d_{TV}(F_q, N(0,1)) \leq 2 \sqrt{\frac{q-1}{3q}} \sqrt{\text{cum}_4(F_q)}.
\]
The result now follows immediately, since each variable \( \sqrt{\frac{2l+1}{2l+1}} \left\{ \frac{\hat{C}_l}{C_l} - 1 \right\} \) has unit variance, and is precisely an element of the second Wiener chaos associated with \( T \).

It is simple to verify numerically that the convergence \( \text{(9)} \) takes place rather fast. For instance, for \( l = 100 \), the bound in total variation is of the order of 2%, while for \( l = 1000 \) we deduce an order of 0.6%.

We stress that the previous results heavily rely on the Gaussian assumption, and cannot be easily extended to the framework of non-Gaussian and isotropic spherical fields. The main reason supporting this claim is contained in the references [3], where it is shown that, under isotropy, the coefficients \( a_{lm} \) are independent if and only if the underlying field is Gaussian, and this despite the fact that they are always uncorrelated by construction. In other words, sampling independent, non-Gaussian random coefficients to generate maps according to \( (1) \) will always yield an anisotropic random field. The dependence structure among the coefficients \( \{a_{lm}\} \) is in general quite complicated, albeit it can be neatly characterized in terms of the group representation properties of \( SO(3) \) (see [28] and [29]). In view of this, to derive any asymptotic result for \( \hat{C}_l \) under non-Gaussianity assumptions for \( T \), is by no means trivial and still almost completely open for research.

1.4 High-frequency Gaussianity

A different form of asymptotic theory has been addressed in an apparently unrelated stream of research, for instance in [28].

Definition 3 (HFG). Let \( T(x) \) be an isotropic, finite variance spherical random field, and recall the notation \( (2) \) and \( (3) \). We say that \( T(x) \) is high-frequency Gaussian (HFG) whenever
\[
\frac{T_l(x)}{\sqrt{\text{Var} \{T_l(x)\}}} \xrightarrow{\text{law}} N(0,1), \text{ as } l \to \infty,
\]
for every fixed \( x \in S^2 \).
Remark. It is more delicate to define HFG involving convergence in the sense of finite dimensional distributions. Indeed, in [28] it is shown that, even if relation (10) holds, the finite-dimensional distributions of order \( \geq 2 \) of the field \( x \mapsto T_1(x)/\sqrt{\text{Var}\{T_1(x)\}} \) may not converge to any limit.

It is clear that a Gaussian field is asymptotically Gaussian: however, as shown in [28], characterizing non-Gaussian fields that are HFG can be a difficult task, even if the underlying field \( T \) is a simple transformation (for instance, the square) of some Gaussian random function. Conditions for the HFG property to hold in some non-Gaussian circumstances are given in [28], by using group representations – yielding some interesting connection with random walks on hypergroups associated with the power spectrum of \( T \). We stress that the possible existence of HFG behaviour entails deep consequences on CMB data analysis. On one hand, in fact, parameter estimation on CMB data is largely dominated by likelihood approaches, whence an asymptotically Gaussian behaviour would great simplify the implementation of optimal procedures. On the other hand, testing for non-Gaussianity is a key ingredient in the validation of the so-called inflationary scenarios, and the possible existence of high frequency Gaussian components for non-Gaussian models might set a theoretical limit to the investigation in this area.

1.5 Purpose and plan

Our purpose in this paper is to investigate the relationships between the HFG and HFE properties under an assumption of Gaussian subordination, that is, by considering fields \( T \) that can be written as a deterministic function of some isotropic, real-valued Gaussian field. We will mainly focus on the case of polynomial subordinations, where the polynomials are of the Hermite type. Note also that Gaussian subordination is the favoured framework for CMB modeling in a non-Gaussian setting (see e.g. [4], [17], [45]).

Our main finding is that, despite their apparent independence, the HFG and HFE properties will turn out to be very close in a broad class of circumstances, suggesting that ergodicity (and hence the possibility to draw asymptotically justifiable statistical inferences) and asymptotic Gaussianity are very tightly related in a high-resolution setting. This may lead, we believe, to important characterizations of Gaussian random fields, and to a better understanding of the conditions for the validity of statistical inference procedures based on observations drawn from a unique realizations of a compactly supported random field, as in the spherical case.

The plan of this paper is as follows: in Section 2 we state and prove our main result, establishing necessary and sufficient conditions for ergodicity and Gaussianity and exploring the link between them. Indeed, these conditions turn out to be extremely close, so that in Section 3 we can indeed discuss more thoroughly a special case of practical relevance, namely the quadratic case. Section 4 is devoted to further discussion and directions for further research.

2 A general statement about Gaussian subordinated fields

The two notations (1) and (2) are adopted throughout the sequel. Let us first recall a few basic facts and definitions.

(1) The first point concerns a characterization of isotropy in terms of angular power spectra. Indeed, as discussed in [17], [29], if a random field is isotropic with finite fourth-order moment,
then there exists necessarily an array \( \{ T_{l_1l_2}^{l_4l_4}(L) \} \) such that
\[
\operatorname{cum} \{ a_{l_1m_1}, a_{l_2m_2}, a_{l_3m_3}, a_{l_4m_4} \}
= \sum_{LM} (-1)^M \left( \begin{array}{ccc} l_1 & l_2 & L \\ m_1 & m_2 & M \end{array} \right) \left( \begin{array}{ccc} l_3 & l_4 & L \\ m_3 & m_4 & -M \end{array} \right) (2L + 1) T_{l_1l_2}^{l_4l_4}(L).
\] (11)

In general, the symbol \( \operatorname{cum} \{ X_1, ..., X_m \} \) denotes the joint cumulant of the random variables \( X_1, ..., X_m \). Also, we label as usual \( \{ T_{l_1l_2}^{l_4l_4}(L) \} \) the cumulant trispectrum of the random field (see for instance [17], [29]); as made clear by our notation, the quantity \( T_{l_1l_2}^{l_4l_4}(L) \) does not depend on \( m_1, m_2, m_3, m_4 \) (this phenomenon is analogous to the fact that the power spectrum only depends on the frequency \( l \) – see [29] for a discussion of this point). On the right-hand side of (11), we have also introduced the well-known Wigner’s coefficients, which arise in the group representation theory of \( SO(3) \) and are discussed at length in many excellent monographs on the quantum theory of angular momentum – see e.g. [23], [43], [44]. For future reference, we also recall that the Wigner’s 3j coefficients are equivalent, up to normalization and phase factor, to the Clebsch-Gordan coefficients given by (see e.g. [43])
\[
C_{l_1m_1l_2m_2}^{LM} = (-1)^{l_1+l_2+m_3} \sqrt{2L+1} \left( \begin{array}{ccc} l_1 & l_2 & L \\ m_1 & m_2 & M \end{array} \right). \] (12)

As noted by [17], geometrically the multipoles \( (l_1, l_2, l_3, l_4) \) can be viewed as the sides of a quadrilateral, and \( L \) as one of its main diagonals; \( L \) is also the shared size of the two triangle formed by the corresponding pairs of side. Clebsch-Gordan coefficients ensure that the triangle conditions are satisfied, indeed they are different from zero only if \( l_1 \leq l_2 + L, \ l_2 \leq l_1 + L, \) and \( L \leq l_1 + l_2. \)

(I) We shall sometimes label a point \( x \) of the sphere \( S^2 \) in terms of its spherical coordinates, that is, \( x = (\vartheta, \varphi) \), where \( 0 \leq \vartheta \leq \pi \) and \( 0 \leq \varphi < 2\pi \).

(III) Easy considerations yield the important fact that, for any isotropic random field \( T \),
\[
T_l(\vartheta, \varphi)^{\text{law}} = T_l(\overline{N}) = \sum_{lm} a_{lm} Y_{lm}(\overline{N})^{\text{law}} = a_0 \sqrt{2l+1 \over 4\pi},
\]
where we denote by \( \overline{N} := (0,0) \) the North Pole of the sphere and by “\(^{\text{law}} \)” the equality in law between two random elements.

(IV) It is immediate that, if \( T \) is isotropic, then for every deterministic function \( F \) the subordinated random application \( x \mapsto F(T(x)) \) is also isotropic. Moreover, if \( F(T(x)) \) is square integrable, then \( F(T(\cdot)) \) also admits a harmonic expansion analogous to (I). One specific instance of this situation is obtained by choosing \( T \) to be Gaussian and isotropic, and \( F \) to be any of the Hermite polynomials \( \{ H_q : q \geq 0 \} \) (in this case, one talks about a Gaussian subordination of the Hermite type). We recall that the polynomials \( H_q \) are such that \( H_q = \delta^{q} \mathbf{1} \), where \( \mathbf{1} \) stands for the function which is constantly equal to one, \( \delta^{0} \) is the identity, and \( \delta^{q} \ (q \geq 1) \) represents the \( q \)-th iteration of the divergence operator \( \delta \), acting on smooth functions as \( \delta f(x) = x f(x) - f'(x) \).
For instance \( H_0 = 1, H_1 (x) = x, H_2 (x) = x^2 - 1 \), and so on. When \( T \) is Gaussian, we adopt the notation

\[
H_q (T (x)) := T_q (x) = \sum_{l=0}^{\infty} T_{l; q} (x), \quad x \in S^2, \quad q \geq 2,
\]

where

\[
T_{l; q} (x) = \sum_{m=-l}^{l} a_{lm; q} Y_{lm} (x)
\]

is the \( l \)th frequency component of \( T_q \), with \( a_{lm; q} \) the associated harmonic coefficients. We shall also write \{\( C_l; q \): \( l \geq 0 \)\} and \{\( T_{l; q} (L: q) \)\}, respectively, for the power spectrum and for the cumulant trispectrum of \( T_q \), as introduced at Point (1). According to [28, Theorem 3], one has that \( C_{l; q} \) admits the following expansion in terms of the power spectrum \{\( C_l \)\} of \( T \):

\[
C_{l; q} = q! \sum_{l_1,\ldots,l_q=0}^{\infty} C_{l_1} \cdots C_{l_q} \frac{4\pi}{2l+1} \left\{ \prod_{l=1}^{q} \frac{2l_1 + 1}{4\pi} \right\} \sum_{L_1,\ldots,L_q=0} \left\{ C_{L_1,\ldots,L_q} (L: q) \right\}^2,
\]

where \( C_{L_1,\ldots,L_q} (L: q) \) indicates a convolution of Clebsch-Gordan coefficients, that is

\[
C_{L_1,\ldots,L_q} (L: q) := \sum_{\lambda_1,\ldots,\lambda_q = 0}^{\infty} \sum_{\mu_1,\ldots,\mu_q = 0} \delta_{\lambda_1,\mu_1} \cdots \delta_{\lambda_q,\mu_q} \left\{ C_{\lambda_1,\mu_1} \cdots C_{\lambda_q,\mu_q} \right\}.
\]

(\( V \)) An easy but important remark is the following. Since the expansion (11) is in order, the law of a centered isotropic Gaussian field \( T \) is completely encoded by the power spectrum \{\( C_l \): \( l \geq 0 \)\}. This is a consequence of the fact that, in this case, the array \{\( a_{lm} : l \geq 0, \quad m = 0,\ldots,l \)\} is composed of independent Gaussian random variables such that: (i) \( a_{l0} \) is real-valued, and (ii) for every \( m \geq 1 \), the coefficient \( a_{lm} \) has independent and equidistributed real and imaginary parts.

As anticipated, we shall now prove some new connections between HFE and HFG spherical fields (see Definitions [1] and [3]), in the special case of fields of the type \( T_q \), as defined in [13]. In particular, our main finding (as stated in Theorem [4]) Note that the conditions appearing in the following statement involve the coefficients \( C_{l; q} \) given in (13), and that these coefficients are completely determined by the power spectrum of the underlying Gaussian field \( T \).

**Theorem 4** Let \( q \geq 2 \), and define \( T_q \) according to (13), where \( T \) is Gaussian and isotropic. Let \( T_{l; q} (L: q) \) be the reduced trispectrum of \( T \). Introduce the notation

\[
w_{1l} (L) := \left( C_{l00}^{L0} \right)^2 \quad \text{and} \quad w_{2l} (L) = \frac{(2L + 1)}{(2l + 1)^2},
\]

in such a way that

\[
\sum_{L=0}^{2l} w_{1l} (L) = \sum_{L=0}^{2l} w_{2l} (L) = 1.
\]

Then, the following holds.
1. the random field $T_q$ is high-frequency Gaussian if and only if
\[
\lim_{l \to \infty} \sum_{L=0}^{2l} w_{1l}(L) \frac{T_{il}^{il}(L; q)}{C_{ilq}^2} = 0. \tag{17}
\]

2. On the other hand, $T_q$ is high-frequency ergodic if and only if
\[
\lim_{l \to \infty} \sum_{L=0}^{2l} w_{2l}(L) \frac{T_{il}^{il}(L; q)}{C_{ilq}^2} = 0. \tag{18}
\]

Before proving Theorem 4, we shall note that \(\{C_{il00}\}^2\) is different from zero only for \(L\) even, and \(T_{il}^{il}(L)\) is not in general positive-valued. Moreover, in view of the forthcoming Lemma 5, also in (18) the sum runs only over even values of \(L\).

Lemma 5 \(T_{il}^{il}(L)\) is zero when \(L\) is odd

Proof. From [17, Eq. (17)], we infer that, in general,
\[
T_{il_l2}^{il_l2}(L) = (-1)^{l_1 + l_2 + L} T_{il_l2}^{il_l2}(L). 
\]

Considering the case \(l_1 = l_2 = l_3 = l_4 = l\), we obtain the desired result.

Proof of Theorem 4. (Proof of 1.) Consider the random spherical field
\[
(\vartheta, \phi) \mapsto \hat{T}_{lq}(\vartheta, \phi) := \frac{T_{lq}(\vartheta, \phi)}{\sqrt{\text{Var}\{T_{lq}(\overline{N})\}}} , \quad (\vartheta, \phi) \in [0, \pi] \times [0, 2\pi),
\]
where \(\overline{N}\) is the North Pole, and observe that, by isotropy and for every \((\vartheta, \phi),\)
\[
\hat{T}_{lq}(\vartheta, \phi) \xrightarrow{\text{law}} \frac{a_{l0}}{\sqrt{4\pi C_{ilq}}}.
\]
The field \(\hat{T}_{lq}\) is mean-zero and has unit variance: since it also belong to the \(q\)th Wiener chaos associated with \(T\), we can deduce from the results in [31] it is asymptotically Gaussian if and only if
\[
\lim_{l \to \infty} \frac{1}{C_{ilq}^2} \text{cum}_4 \{a_{l0q}\} = 0.
\]
As discussed e.g. in [17] and [29], isotropy entails that we can write the fourth-order cumulant as
\[
\text{cum}_4 \{a_{l0q}\} = \sum_{LM} (-1)^M \left( \begin{array}{ccc} l & l & L \\ 0 & 0 & M \end{array} \right) \left( \begin{array}{ccc} l & l & L \\ 0 & 0 & -M \end{array} \right) (2L + 1) T_{il}^{il}(L)
\]
\[
= \sum_{L} \left( \begin{array}{ccc} l & l & L \\ 0 & 0 & 0 \end{array} \right)^2 (2L + 1) T_{il}^{il}(L),
\]
so that the field is asymptotically Gaussian if and only if
\[
\lim_{l \to \infty} \frac{1}{C_{l q}^2} \sum_{L} \left( \begin{array}{ccc} l & l & L \\ 0 & 0 & 0 \end{array} \right)^2 (2L + 1) T_{ll}^{II}(L) = 0 .
\] (19)

Since relation (12) is in order, we write
\[
\left( \begin{array}{ccc} l & l & L \\ 0 & 0 & 0 \end{array} \right)^2 (2L + 1) = \{ C_{l q}^{L0} \}^2,
\]
extailing in turn that
\[
\sum_{L} \left( \begin{array}{ccc} l & l & L \\ 0 & 0 & 0 \end{array} \right)^2 (2L + 1) = \sum_{L=0}^{2l} \{ C_{l q}^{L0} \}^2 \sum_{L=0}^{2l} \sum_{M=-L}^{L} \{ C_{l q}^{LM} \}^2 \equiv 1 ,
\]
where the second equality follows from the fact that Clebsch-Gordan coefficients \( C_{l_1 m_1, l_2 m_2}^{l_3 m_3} \) are different from zero only for \( m_3 = m_1 + m_2 \), and the third equality is a consequence from the orthonormality properties of the coefficients (which are the elements of unitary matrices whose rows are indexed by \( m_1, m_2 \) and whose columns are indexed by \( l_3, m_3 \)). We therefore have
\[
\frac{1}{C_{l q}^2} \sum_{m_1 m_2} \{ C_{l q}^{m_1 m_2} a_{l q} \} = \frac{1}{C_{l q}^2} \sum_{L} \{ C_{l q}^{L0} \}^2 T_{ll}^{II}(L) ,
\]
yielding the desired conclusion.

(Proof of 2.) On the other hand, we obtain also
\[
E \left\{ \frac{\hat{C}_{l q}}{C_{l q}} - 1 \right\}^2 = Var \left\{ \frac{\hat{C}_{l q}}{C_{l q}} - 1 \right\}
\]
\[
= \frac{1}{(2l + 1)^2} \frac{1}{C_{l q}^2} \sum_{m_1 m_2} \sum_{L} \sum_{M} (-1)^{m_1 + m_2} \{ C_{l q}^{m_1 m_2} a_{l m_1, q} \} \{ C_{l q}^{m_1 m_2} a_{l m_2, q} \} + \frac{2}{(2l + 1)^2} \frac{1}{C_{l q}^2} \sum_{m} \{ E |a_{l m_1, q}|^2 \}^2
\]
\[
= \frac{1}{(2l + 1)^2} \frac{1}{C_{l q}^2} \sum_{m_1 m_2} (-1)^{m_1 + m_2} \{ a_{l m_1, q}, a_{l,-m_1, q}, a_{l m_2, q}, a_{l,-m_2, q} \} + \frac{2}{(2l + 1)}
\]
\[
= \frac{2}{(2l + 1)^2} \frac{1}{C_{l q}^2} \sum_{m_1 m_2} \sum_{L} (-1)^{M + m_1 + m_2} \left( \begin{array}{ccc} l & l & L \\ m_1 & m_2 & M \end{array} \right) \times
\]
\[
\times \left( \begin{array}{ccc} l & l & L \\ -m_1 & -m_2 & -M \end{array} \right) (2L + 1) T_{ll}^{II}(L) + \frac{2}{(2l + 1)}
\]
\[
= \frac{2}{(2l + 1)^2} \frac{1}{C_{l q}^2} \sum_{L=0}^{2l} (2L + 1) T_{ll}^{II}(L) + \frac{2}{(2l + 1)}
\] (23)
It is simple to notice that
\[
\sum_{L=0}^{2l} (2L + 1) = \frac{2l(2l + 1)}{2} + 2l + 1 = (2l + 1)^2,
\]
so that we have
\[
E \left\{ \frac{\hat{C}_{lq}}{C_{lq}} - 1 \right\}^2 = 2 \sum_{L=0}^{2l} w_{lL}^2 T_{ll}^H (L) + \frac{2}{(2l + 1)}, \quad \text{where } w_{lL} \geq 0 \text{ and } \sum_{L=0}^{2l} w_{lL} = 1.
\]
The result now follows immediately.

**Remark.** Note that
\[
\{ C_{0000}^{L_0} \}^2 = \frac{(2L + 1)(2l + L)!^2}{(2l + 1)^2} \frac{L!(2l + L)!}{L!(2l + L)!} \leq \frac{1}{(2l + 1)}
\]
\[
w_{2l}(L) = \frac{(2L + 1)}{(2l + 1)^2} \leq \frac{1}{2l + 1}
\]
Note also that in the Gaussian case (e.g., \( q = 1 \)) we have \( T_{ll}^H (L) \equiv 0 \), whence
\[
E \left\{ \frac{\hat{C}_{lq}}{C_{lq}} - 1 \right\}^2 = \frac{2}{(2l + 1)} \to 0,
\]
as expected.

The previous result strongly suggests that the conditions for asymptotic Gaussianity (HFG) and for ergodicity (HFE) should be tightly related. Indeed we conjecture that HFE and HFG are equivalent in the case of Hermite type Gaussian subordinations (and most probably even in more general circumstances). However, proving this claim seems analytically too demanding at this stage, so that for the rest of the paper we content ourselves with a detailed analysis of quadratic Gaussian subordinations. In particular, we believe that the content of the forthcoming Section 12 (which is already quite technical) may provide the seed for a complete understanding of the HFG-HFE connection.

**Remark 6** It should be noted that the reduced trispectrum satisfies (see [13, Eq. (16)])
\[
T_{ll}^H (L') = \sum_{L} (2L + 1) \left\{ \begin{array}{ccc} l & l & L \\ l' & l & L' \end{array} \right\} T_{ll}^H (L).
\]

In the previous remark, we introduced the well-known Wigner’s 6j coefficients, which intertwine alternative coupling schemes of three quantum angular momenta (see [6], [3] for further properties and much more discussion). Their relationship with Wigner’s 3j coefficients is provided by the identity
\[
\{ a \ b \ c \quad d \ e \ f \} := \sum_{\alpha, \beta, \gamma, \ \epsilon, \delta, \phi} (-1)^{\epsilon+\phi+\epsilon+\phi} \left( \begin{array}{ccc} a & b & e \\ \alpha & \beta & \epsilon \end{array} \right) \left( \begin{array}{ccc} c & d & e \\ \gamma & \delta & -\epsilon \end{array} \right) \left( \begin{array}{ccc} a & d & f \\ \alpha & \delta & -\phi \end{array} \right) \left( \begin{array}{ccc} c & b & f \\ \gamma & \beta & \phi \end{array} \right)
\]
(see [13], Chapter 9, for analytic expressions and a full set of properties).
3 The quadratic case

3.1 The class $\mathcal{D}$ and main results

As anticipated, the purpose of this section is to provide a more detailed and explicit analysis of the quadratic case $q = 2$. For simplicity, in the sequel we consider a centered Gaussian isotropic spherical field $T$ such that $Var(T(x)) = \sum_l (2l + 1) C_l / 4\pi = 1$, where $\{C_l\}$ is as before the power spectrum of $T$. We start by recalling the notation

$$T_2(x) = H_2(T(x)) = \sum_{l_1,l_2=1}^{\infty} \sum_{m_1m_2} a_{l_1m_1} a_{l_2m_2} Y_{l_1m_1}(x) Y_{l_2m_2}(x) - 1 ,$$

(25)

where $T$ is isotropic, centered and Gaussian. Our first result can be seen as a consequence of formula (15) (or, more generally, of the results of [28]). Here, we provide a proof for the sake of completeness.

**Lemma 7** The angular power spectrum of the squared random field (25) is given by

$$C_{l;2} = E|a_{lm;2}|^2 = 2\sum_{l_1l_2} C_{l_1} C_{l_2} \left( l_1 \atop 0 \quad l_2 \atop 0 \quad l \atop 0 \right)^2 \frac{(2l+1)(2l+1)}{4\pi} .$$

**Proof.** Recall first that $Y_{00}(x) \equiv (4\pi)^{-1/2}$, see [43], equation 5.13.1.1. Hence, in view of (25), we have that, for $l = 0$,

$$a_{00;2} = \int_{S^2} \left\{ \sum_{l_1l_2} \sum_{m_1m_2} a_{l_1m_1} a_{l_2m_2} Y_{l_1m_1}(x) Y_{l_2m_2}(x) - 1 \right\} Y_{00}(x) dx$$

$$= \frac{1}{\sqrt{4\pi}} \sum_{l_1l_2} \sum_{m_1m_2} a_{l_1m_1} a_{l_2m_2} \left\{ \int_{S^2} Y_{l_1m_1}(x) Y_{l_2m_2}(x) dx \right\} - \sqrt{4\pi}$$

$$= \frac{1}{\sqrt{4\pi}} \sum_{l_1l_2} \sum_{m_1m_2} a_{l_1m_1} a_{l_2m_2} \delta_{l_1l_2} \delta_{m_1m_2} - \sqrt{4\pi}$$

$$= \frac{1}{\sqrt{4\pi}} \sum_{lm} |a_{lm}|^2 - \sqrt{4\pi} .$$

It follows that

$$Ea_{00;2} = \sum_{lm} \frac{2l+1}{\sqrt{4\pi}} C_l - \sqrt{4\pi} = \sqrt{4\pi} \left\{ \sum_{lm} \frac{2l+1}{4\pi} C_l - 1 \right\} = 0 ,$$

and

$$EH_2(T(x)) = E \sum_{l=0}^{\infty} a_{lm;2} Y_{lm}(x) = E a_{00;2} Y_{00}(x) = 0 ,$$

the second step following because $Ea_{lm} = 0$ for all $l > 0$ under isotropy (see [2]). Indeed we have (from (25), and in view of (14))

$$a_{lm;2} = \int_{S^2} \sum_{l_1l_2} \sum_{m_1m_2} a_{l_1m_1} a_{l_2m_2} Y_{l_1m_1}(x) Y_{l_2m_2}(x) Y_{lm}(x) dx$$
Now note that the constant term \(-1\) has no effect for \(l \geq 1\), because

\[
\int_{S^2} Y_{lm}(x)\, dx = 0 \quad \text{for all } l \geq 1.
\]

Now

\[
E_{l_1m_2} = \sum_{l_1} \sum_{m_1} C_{l_1} (-1)^{m_1} \begin{pmatrix} l_1 & l_2 & l \\ m_1 & -m_1 & -m \end{pmatrix} \begin{pmatrix} l_1 \ 0 \ 0 \\ m_1 \ -m_1 \ 0 \end{pmatrix} \sqrt{\frac{(2l_1+1)(2l_2+1)(2l+1)}{4\pi}}.
\]

in view of the well-known properties (\cite{H3}, Eq. (8.5.1.1) and Eq. (8.7.1.2))

\[
\begin{pmatrix} l_1 \ l_1 \ 0 \\ 0 \ 0 \ 0 \\ m_1 \ -m_1 \ 0 \end{pmatrix} = \frac{1}{\sqrt{2l_1+1}}, \quad \sum_{m_1} (-1)^{m_1} \begin{pmatrix} l_1 & l_1 & l \\ m_1 & -m_1 & 0 \end{pmatrix} = \sqrt{2l_1+1} \delta_l^0.
\]

Hence we have, as expected, \(E_{l_1m_2} = 0\) for all \(l\). Furthermore

\[
E |a_{l_1m_2}|^2 = E \left\{ \sum_{l_1} \sum_{m_1} a_{l_1m_1} a_{l_2m_2} \begin{pmatrix} l_1 & l_2 & l \\ m_1 & m_2 & -m \end{pmatrix} \begin{pmatrix} l_1 \ 0 \ 0 \\ m_1 \ -m_1 \ 0 \end{pmatrix} \sqrt{\frac{(2l_1+1)(2l_2+1)(2l+1)}{4\pi}} \right\}
\]

\[
= 2 \sum_{l_1l_2} C_{l_1} C_{l_2} \sum_{m_1m_2} \begin{pmatrix} l_1 & l_2 & l \\ m_1 & m_2 & -m \end{pmatrix} \begin{pmatrix} l_1 \ 0 \ 0 \\ m_1 \ -m_1 \ 0 \end{pmatrix} \sqrt{\frac{(2l_1+1)(2l_2+1)(2l+1)}{4\pi}}
\]

\[
= 2 \sum_{l_1l_2} C_{l_1} C_{l_2} \begin{pmatrix} l_1 \ l_2 \ l \\ 0 \ 0 \ 0 \end{pmatrix} \sqrt{\frac{(2l_1+1)(2l_2+1)(2l+1)}{4\pi}},
\]

and the proof is completed. \(\blacksquare\)

**Remark.** Note that

\[
\text{Var} \left\{ T^2(x) \right\} = \sum_l \frac{2l+1}{4\pi} C_l
\]

\[
= 2 \sum_{l_1l_2} C_{l_1} C_{l_2} \frac{(2l_1+1)(2l_2+1)}{4\pi} \left\{ \sum_l \frac{2l+1}{4\pi} \begin{pmatrix} l_1 \ l_2 \ l \\ 0 \ 0 \ 0 \end{pmatrix} \right\}^2
\]

\[
= 2 \sum_{l_1l_2} C_{l_1} C_{l_2} \frac{(2l_1+1)(2l_2+1)}{(4\pi)^2} = 2 \text{Var} \left\{ T(x) \right\}^2,
\]

14
as expected from standard property of Gaussian variables. Here we have used again

\[ \sum_l (2l + 1) \left( \begin{array}{ccc} l_1 & l_2 & l \\ 0 & 0 & 0 \end{array} \right)^2 \equiv 1. \]

Our strategy is now the following. We shall first define a very general class, noted \( \mathcal{D} \), of quadratic models in terms of the power spectrum of the underlying Gaussian field, and then we shall show that the two notions of HFG and HFE coincide within \( \mathcal{D} \).

**Definition 8** The centered Gaussian isotropic field \( T \) is said to belong to the class \( \mathcal{D} \) if there exist real numbers \( \alpha, \beta \) such that

1. \( \alpha \in \mathbb{R} \) and \( \beta \geq 0 \)
2. \( \sum_{l=0}^{\infty} l^{-\alpha+1} e^{-\beta l} < \infty \)
3. there exists constants \( c_1, c_2 > 0 \) such that

\[ 0 < c_1 \leq \lim \inf_{l \rightarrow \infty} \frac{C_l}{l^{-\alpha} e^{-\beta l}} \leq \lim \sup_{l \rightarrow \infty} \frac{C_l}{l^{-\alpha} e^{-\beta l}} \leq c_2 < \infty \]  

(27)

**Remarks.**

1. As a first approximation, the class \( \mathcal{D} \) contains virtually all models that are relevant for CMB modeling in the case of a quadratic Gaussian subordination. For instance, Sachs-Wolfe models with the so-called Bardeen’s potential entail a polynomial decay of the \( C_l \) (\( \beta = 0 \)), whereas the so-called Silk damping effect entails an exponential decay of the power spectrum of primary CMB anisotropies at higher \( l \). We refer again to textbooks such as [12], [13] for more discussion on these points.

2. Note that Condition 2 in the definition of \( \mathcal{D} \) implies that the parameters \( \alpha, \beta \) must be such that either \( \beta = 0 \) and \( \alpha > 2 \), or \( \beta > 0 \) and \( \alpha \in \mathbb{R} \) (with no restrictions).

The next statement is the main achievement of this section. It shows in particular, that the HFG and HFE exhibit the same phase transition within the class \( \mathcal{D} \).

**Theorem 9** Let \( T_2 = H_2(T) \), where the centered Gaussian isotropic field \( T \) is an element of the class \( \mathcal{D} \). Then, the following three conditions are equivalent

(i) \( T_2 \) is HFG

(ii) \( T_2 \) is HFE

(iii) \( \beta > 0 \) and \( \alpha \in \mathbb{R} \).
3.2 Proof of Theorem 9

From [28, Section 6], we already know that Conditions (i) and (iii) in the statement of Theorem 9 are equivalent. The proof of the remaining implication (ii) ⇐⇒ (iii) is divided in several steps.

We start by showing that, if (iii) is not verified, then the angular power spectrum of the transformed field, under broad conditions, exhibits the same behaviour as the angular power spectrum of the subordinating field.

Lemma 10 Suppose \( \beta = 0 \) and \( \alpha > 2 \), then

\[
3 \times \frac{2^{\alpha}}{4\pi} C_l \frac{\sigma_1^2}{c_2} \leq C_{l/2} \leq \frac{c_2}{c_1 \pi} \{ 2 \zeta(\alpha - 1) + \zeta(\alpha) \} C_{l/2} = O(C_l),
\]

where \( \zeta(.) \) denotes the Riemann zeta function.

Proof. We have

\[
\sum_{l_1 l_2 \leq l} C_{l_1} C_{l_2} \left( \begin{array}{ccc} l_1 & l_2 & l \\ 0 & 0 & 0 \end{array} \right) \frac{(2l_1 + 1)(2l_2 + 1)}{4\pi} \leq 2 \sum_{l_1 \leq l} C_{l_1} C_{l_2} \left( \begin{array}{ccc} l_1 & l_2 & l \\ 0 & 0 & 0 \end{array} \right) \frac{(2l_1 + 1)(2l_2 + 1)}{4\pi} \leq 2 \frac{c_2}{c_1} C_{l/2} \sum_{l_1 \leq l_2} C_{l_1} \left( \begin{array}{ccc} l_1 & l_2 & l \\ 0 & 0 & 0 \end{array} \right) \frac{(2l_1 + 1)(2l_2 + 1)}{4\pi},
\]

because \((l_1 \lor l_2) > l/2\) by the triangle conditions and \( \sup_{l_2 \geq l/2} C_{l_2}/C_{l/2} \leq c_2/c_1 \). Now

\[
\sum_{l_1 \leq l_2} C_{l_1} \left( \begin{array}{ccc} l_1 & l_2 & l \\ 0 & 0 & 0 \end{array} \right) \frac{(2l_1 + 1)(2l_2 + 1)}{4\pi} \leq \sum_{l_1} C_{l_1} \frac{(2l_1 + 1)}{4\pi} \sum_{l_2} (2l_2 + 1) \left( \begin{array}{ccc} l_1 & l_2 & l \\ 0 & 0 & 0 \end{array} \right) \frac{(2l_1 + 1)}{4\pi} = \sum_{l_1} C_{l_1} \frac{(2l_1 + 1)}{4\pi} < \infty.
\]

More precisely

\[
\sum_{l_1} C_{l_1} \frac{(2l_1 + 1)}{4\pi} \leq \frac{c_2}{4\pi} \sum_l (2l + 1)l^{-\alpha} \leq \frac{c_2}{4\pi} \{ 2 \zeta(\alpha - 1) + \zeta(\alpha) \}.
\]

Hence

\[
C_{l/2} \leq \frac{c_2}{2c_1 \pi} \{ 2 \zeta(\alpha - 1) + \zeta(\alpha) \} C_{l/2}.
\]

The upper bound is then established. For the lower bound, it is sufficient to show that

\[
\sum_{l_1 l_2} C_{l_1} C_{l_2} \left( \begin{array}{ccc} l_1 & l_2 & l \\ 0 & 0 & 0 \end{array} \right) \frac{(2l_1 + 1)(2l_2 + 1)}{4\pi} \geq \sum_{l_2} C_{l_1} C_{l_2} \left( \begin{array}{ccc} l_1 & l_2 & l \\ 0 & 0 & 0 \end{array} \right) \frac{3(2l_2 + 1)}{4\pi} \geq 32^{\alpha} \frac{c_1^2}{c_2} \sum_{l_2} \left( \begin{array}{ccc} l_1 & l_2 & l \\ 0 & 0 & 0 \end{array} \right) \frac{(2l_2 + 1)}{4\pi} \geq \frac{3}{4\pi} C_{l/2} \frac{c_1^2}{c_2}.
\]

as claimed. ■
Loosely, the previous Lemma [10] states that, under algebraic decay, the rate of convergence to zero of the angular power spectrum is not affected by a quadratic transformation, i.e. $C_{t:2} \simeq C_t$.

The following result holds for fixed $l$, and it is therefore not related to the high-frequency asymptotic behaviour of the power spectrum $\{C_l\}$ (see [28] for related computations). Note that we use the notation

$$\hat{C}_{t:2} = \frac{1}{2l+1} \sum_{m=-l}^{l} |a_{lm:2}|^2, \quad \tilde{C}_{t:2} = \frac{C_{t:2}}{C_{t:2}}.$$ 

**Lemma 11** Let $T_2$ be defined by (23). Then we have

$$E\{\tilde{C}_{t:2} - 1\}^2 = \frac{16}{C_{t:2}^2} \sum_{l_1l_2l_3} C_{t_1}^2 C_{t_2} C_{t_3} \left( \begin{array}{ccc} l_1 & l_2 & l \\ 0 & 0 & 0 \end{array} \right)^2 \left( \begin{array}{ccc} l_1 & l_3 & l \\ 0 & 0 & 0 \end{array} \right)^2 \frac{(2l_1 + 1)(2l_2 + 1)(2l_3 + 1)}{(4\pi)^2} + R(l),$$

where for all $l = 1, 2, \ldots$

$$0 \leq R(l) \leq \frac{4}{2l+1}.$$ 

**Proof.** In the sequel, we shall use repeatedly the unitary properties of Clebsch-Gordan coefficients, i.e.

$$\sum_{m_{l_1l_2}} \left( \begin{array}{ccc} l & l & L \\ m_1 & m_2 & M \end{array} \right) \left( \begin{array}{ccc} l & l & L' \\ m_1 & m_2 & M' \end{array} \right) = \frac{\delta^L_{L'} \delta^M_{M'}}{2L+1}. \quad (28)$$

Recalling [20], [21], we need to evaluate

$$\frac{1}{(2l+1)^2 C_{t:2}^2} \sum_{m_{l_1l_2}} \sum \{a_{lm_1}, \bar{a}_{lm_1}, a_{lm_2}, \bar{a}_{lm_2}\}.$$ 

Now

$$\sum_{m_{l_1l_2}} \sum \{a_{lm_1}, a_{l_{-m_1}}, a_{lm_2}, a_{l_{-m_2}}\} =$$

and counting equivalent permutations

\[
= 8 \sum_{l_1 l_2 l_3 l_4 \mu_1 \mu_2 \mu_3 \mu_4} (-1)^{\mu_1+\mu_2+\mu_3+\mu_4} C_{l_1 l_2 l_3 l_4} \begin{pmatrix} l_1 & l_2 & l \\ \mu_1 & \mu_2 & m_1 \end{pmatrix} \begin{pmatrix} l_1 & l_2 & l \\ 0 & 0 & 0 \end{pmatrix} \frac{(2l+1)^2 \prod_{i=1}^{4} (2l_i + 1)}{(4\pi)^2} \times \\
\times \begin{pmatrix} l_1 & l_3 & l \\ -\mu_1 & -\mu_3 & -m_1 \end{pmatrix} \begin{pmatrix} l_1 & l_3 & l \\ 0 & 0 & 0 \end{pmatrix} \left( \begin{array}{ccc} l_4 & l_3 & l \\ \mu_4 & \mu_3 & m_2 \end{array} \right) \begin{pmatrix} l_4 & l_3 & l \\ 0 & 0 & 0 \end{pmatrix} \left( \begin{array}{ccc} l_4 & l_2 & l \\ -\mu_4 & -\mu_2 & m_2 \end{array} \right) \begin{pmatrix} l_4 & l_2 & l \\ 0 & 0 & 0 \end{pmatrix}
\]
\[+ 8 \sum_{l_1 l_2 l_3 l_4 \mu_1 \mu_2 \mu_3 \mu_4} (-1)^{\mu_1+\mu_2+\mu_3+\mu_4} C_{l_1 l_2 l_3 l_4} \begin{pmatrix} l_1 & l_2 & l \\ \mu_1 & \mu_2 & m_1 \end{pmatrix} \begin{pmatrix} l_1 & l_2 & l \\ 0 & 0 & 0 \end{pmatrix} \frac{(2l+1)^2 \prod_{i=1}^{4} (2l_i + 1)}{(4\pi)^2} \times \\
\times \begin{pmatrix} l_3 & l_4 & l \\ \mu_3 & \mu_4 & -m_1 \end{pmatrix} \begin{pmatrix} l_3 & l_4 & l \\ 0 & 0 & 0 \end{pmatrix} \left( \begin{array}{ccc} l_1 & l_3 & l \\ -\mu_1 & -\mu_3 & m_2 \end{array} \right) \begin{pmatrix} l_1 & l_3 & l \\ 0 & 0 & 0 \end{pmatrix} \left( \begin{array}{ccc} l_4 & l_2 & l \\ -\mu_4 & -\mu_2 & m_2 \end{array} \right) \begin{pmatrix} l_4 & l_2 & l \\ 0 & 0 & 0 \end{pmatrix}
\]
\[+ 8 \sum_{l_1 l_2 l_3 l_4 \mu_1 \mu_2 \mu_3 \mu_4} (-1)^{\mu_1+\mu_2+\mu_3+\mu_4} C_{l_1 l_2 l_3 l_4} \begin{pmatrix} l_1 & l_2 & l \\ \mu_1 & \mu_2 & m_1 \end{pmatrix} \begin{pmatrix} l_1 & l_2 & l \\ 0 & 0 & 0 \end{pmatrix} \frac{(2l+1)^2 \prod_{i=1}^{4} (2l_i + 1)}{(4\pi)^2} \times \\
\times \begin{pmatrix} l_2 & l_4 & l \\ -\mu_2 & \mu_4 & m_2 \end{pmatrix} \begin{pmatrix} l_2 & l_4 & l \\ 0 & 0 & 0 \end{pmatrix} \left( \begin{array}{ccc} l_3 & l_4 & l \\ -\mu_3 & -\mu_4 & m_2 \end{array} \right) \begin{pmatrix} l_3 & l_4 & l \\ 0 & 0 & 0 \end{pmatrix} \left( \begin{array}{ccc} l_4 & l_2 & l \\ 0 & 0 & 0 \end{array} \right) \frac{\delta_{\mu_3 \mu_4} \delta_{l_3 l_4}}{2l_3 + 1}
\]

\[= 8 \{ A(m_1, -m_1, m_2, -m_2) + B(m_1, -m_1, m_2, -m_2) + C(m_1, -m_1, m_2, -m_2) \} .
\]

For the first term, note first that \((-1)^{m_1+m_2+\mu_1+\mu_2+\mu_3+\mu_4} \equiv 1\), because the exponent is necessarily even by the properties of Wigner’s coefficients. Moreover, applying iteratively (28)

\[\sum_{m_1 m_2} A(m_1, -m_1, m_2, -m_2)\]

\[= \sum_{l_1 l_2 l_3 l_4 \mu_2 \mu_3 \mu_4} C_{l_1 l_2 l_3 l_4} \begin{pmatrix} l_1 & l_2 & l \\ \mu_2 & \mu_3 & m_2 \end{pmatrix} \begin{pmatrix} l_1 & l_2 & l \\ 0 & 0 & 0 \end{pmatrix} \frac{(2l+1)^2 \prod_{i=1}^{4} (2l_i + 1)}{(4\pi)^2} \times \\
\times \begin{pmatrix} l_4 & l_3 & l \\ -\mu_4 & -\mu_2 & m_2 \end{pmatrix} \begin{pmatrix} l_4 & l_3 & l \\ 0 & 0 & 0 \end{pmatrix} \left( \begin{array}{ccc} l_4 & l_2 & l \\ 0 & 0 & 0 \end{array} \right) \frac{\delta_{\mu_2 \mu_3} \delta_{l_2 l_3}}{2l_3 + 1}
\]

\[= \sum_{l_1 l_2 l_3 l_4} C_{l_1 l_2 l_3 l_4} \begin{pmatrix} l_1 & l_2 & l \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} l_1 & l_2 & l \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} l_1 & l_2 & l \\ 2 & 2 & 2 \end{array} \frac{(2l_1 + 1)(2l_2 + 1)(2l_4 + 1)(2l_1 + 1)}{(4\pi)^2} .
\]

Likewise, for the second term we note that \((-1)^{m_1+m_2+\mu_3+\mu_4} \equiv 1\), and using (24)

\[\sum_{m_1 m_2} (-1)^{m_1+m_2} B(m_1, -m_1, m_2, -m_2)\]
If
\[ \sum_{l_1 l_2 l_3 l_4} C_{l_1} C_{l_2} C_{l_3} C_{l_4} \left\{ \begin{array}{c} l_1 \\ l_2 \\ l_3 \\ l_4 \end{array} \right\} \left( \begin{array}{cccc} 1 & 0 & 0 & 0 \\ l_1 & l_2 & l_3 & l_4 \end{array} \right) \left( \begin{array}{cccc} l_1 & l_2 & l_3 & l_4 \\ 0 & 0 & 0 & 0 \end{array} \right) \right] \times \\
\times \left( \begin{array}{cccc} l_1 & l_2 & l_3 & l_4 \\ 0 & 0 & 0 & 0 \end{array} \right) \left( \begin{array}{cccc} l_1 & l_2 & l_3 & l_4 \\ 0 & 0 & 0 & 0 \end{array} \right) \right) \right) \frac{(2l + 1)^2}{4} \prod_{i=1}^{4} (2l_i + 1) \right]^{1/2}.

Now by Cauchy-Schwartz inequality and recalling that
\[ \left\{ \begin{array}{c} l_1 \\ l_2 \\ l_3 \\ l_4 \end{array} \right\} \leq \frac{1}{2l + 1} \text{ for all } l_1, l_2, l_3, l_4, \]
the previous quantity can be bounded by
\[
\frac{1}{2l + 1} \sum_{l_1 l_2 l_3 l_4} C_{l_1} C_{l_2} C_{l_3} C_{l_4} \left( \begin{array}{cccc} l_1 & l_2 & l_3 & l_4 \\ 0 & 0 & 0 & 0 \end{array} \right) \left( \begin{array}{cccc} l_1 & l_2 & l_3 & l_4 \\ 0 & 0 & 0 & 0 \end{array} \right) \right) \right) \times \\
\times \left( \begin{array}{cccc} l_1 & l_2 & l_3 & l_4 \\ 0 & 0 & 0 & 0 \end{array} \right) \left( \begin{array}{cccc} l_1 & l_2 & l_3 & l_4 \\ 0 & 0 & 0 & 0 \end{array} \right) \right) \right) \right) \frac{(2l + 1)^2}{4} \prod_{i=1}^{4} (2l_i + 1) \right]^{1/2}
= \frac{2l + 1}{4} C_{l_1}^2,
\]
whence
\[
\frac{8}{(2l + 1)^2 C_{l_1}^2} \sum_{m_1 m_2} B(m_1, -m_1, m_2, -m_2) \leq \frac{2}{2l + 1}.
\]

It is easy to see that \( \sum_{m_1 m_2} A(m_1, -m_1, m_2, -m_2) = \sum_{m_1 m_2} C(m_1, -m_1, m_2, -m_2) \). In view of
\[ [23, 23], \]
the statement of the lemma follows easily. ■

The proof of Theorem 1 is now concluded by the following lemma.

**Lemma 12** If \( \beta = 0 \) and \( \alpha > 2 \), then
\[
\lim_{l \to \infty} \inf E \left\{ \tilde{C}_{l,2} - 1 \right\}^2 \geq C_2^2 \left\{ \begin{array}{c} \frac{c_0^3}{2c_1 \pi} \{ 2 \zeta(\alpha - 1) + \zeta(\alpha) \} 2^{\alpha} \end{array} \right\}^{-2} > 0.
\]

If \( \beta > 0 \) and \( \alpha \) is real, then
\[
\lim_{l \to \infty} E \left\{ \tilde{C}_{l,2} - 1 \right\}^2 = 0.
\]

**Proof.** For the first part, from Lemma 11 we can focus on
\[
\frac{1}{C_{l_1}^2} \sum_{l_1 l_2 l_3} C_{l_1}^2 C_{l_2} C_{l_3} \left( \begin{array}{cccc} l_1 & l_2 & l_3 & l_4 \\ 0 & 0 & 0 & 0 \end{array} \right) \left( \begin{array}{cccc} l_1 & l_2 & l_3 & l_4 \\ 0 & 0 & 0 & 0 \end{array} \right) \right) \right) \frac{(2l_1 + 1)(2l_2 + 1)(2l_3 + 1)}{(4\pi)^2}
\]
\[
= \frac{1}{C_{l_1}^{l_2}} \sum_{l_1 l_2} (2l_1 + 1)(2l_2 + 1) C_{l_1} C_{l_2} \left( {l_1 \atop 0} {l_2 \atop 0} \right)^2 \sum_{l_3} C_{l_1} C_{l_3} \left( {l_1 \atop 0} {l_3 \atop 0} \right) \left( \frac{2l_3 + 1}{(4\pi)^2} \right),
\]
which is larger than
\[
\frac{1}{C_{l_1}^{l_2}} \sum_{l_2} (2l_2 + 1) C_{l_1} C_{l_2} \left( {2 \atop 0} {l_2 \atop 0} \right)^2 \sum_{l_3} C_{l_2} C_{l_3} \left( {2 \atop 0} {l_3 \atop 0} \right) \left( \frac{2l_3 + 1}{(4\pi)^2} \right)
\geq \frac{C_{l_1}^{l_2}}{C_{l_1}^{l_2}} \sum_{l_2} (2l_2 + 1) \left( {2 \atop 0} {l_2 \atop 0} \right)^2 \sum_{l_3} \left( {2 \atop 0} {l_3 \atop 0} \right) \left( \frac{2l_3 + 1}{(4\pi)^2} \right) = \frac{C_{l_1}^{l_2} C_{l_2}^{l_2}}{C_{l_1}^{l_2}}.
\]
Now we have proved earlier that in the polynomial case, \( C_{l_1} \sim C_{l_1} \sim l^{-\alpha} \), so the previous ratio does not converge to zero and \( \tilde{C}_{l_1}^{l_2} \) cannot be ergodic; the lower bound provided in the statement of the Lemma follows from previous computations and easy manipulations.

For the second part of the statement, it is sufficient to note that
\[
\frac{1}{C_{l_1}^{l_2}} \sum_{l_1 l_2} (2l_1 + 1)(2l_2 + 1) C_{l_1} C_{l_2} \left( {l_1 \atop 0} {l_2 \atop 0} \right)^2 \sum_{l_3} C_{l_1} C_{l_3} \left( {l_1 \atop 0} {l_3 \atop 0} \right) \left( \frac{2l_3 + 1}{(4\pi)^2} \right)
\leq \sup_l (2l + 1)^{-1} \sum_{l_3} \Gamma_{l_3} \left( C_{l_3} \right) \sum_{l_1 l_2} \Gamma_{l_1} \Gamma_{l_2} \left( C_{l_1 l_2} \right)^2 \leq \sup_l \sum_{l_3} \Gamma_{l_3} \left( C_{l_3} \right)^2 \sum_{l_1 l_2} \Gamma_{l_1} \Gamma_{l_2} \left( C_{l_1 l_2} \right)^2,
\]
so the condition is met, just as for the standard case of \( \Sigma \). □

**Remarks.**

1. By inspection of the previous proof, we note that we have shown how the sufficient condition for asymptotic Gaussianity (HFG) is also such for ergodicity (HFE). More precisely, we have proved that
\[
\lim_{l \to \infty} \sup \frac{1}{\sum_{l_1 l_2} \Gamma_{l_1} \Gamma_{l_2} \left( C_{l_1 l_2} \right)^2} = \lim_{l \to \infty} \sup P(Z_1 = l_1 | Z_2 = l_2) = 0,
\]
where \( \{Z_l\} \) is the Markov chain defined in \( \Sigma \), Eq. (57) and (58) is a sufficient condition for the HFG (see \( \Sigma \), Proposition 9) and also a sufficient condition to have \( \lim_{l \to \infty} E \left( \tilde{C}_l - 1 \right)^2 = 0 \).

2. In principle, the case \( q = 3 \) can be dealt along similar lines.

3. (On Cosmic Variance) Loosely speaking, the epistemological status of Cosmological research has always been the object of some debate, as in some sense we are dealing with a science based on a single observation (our observed Universe). In the CMB community, this issue has been somewhat rephrased in terms of so-called Cosmic Variance - i.e., it takes as common knowledge that parameters relating only to lower multipoles (such as the value of \( C_l \), for small values of \( l \)) are inevitably affected by an intrinsic uncertainty which cannot be eliminated (the variability due to the peculiar realization of the random field that we are able to observe), whereas this effect is taken to disappear at higher \( l \) (implicitly assuming that something like the HFE should always hold). Our result seems to point out, apparently for the first time, the very profound role that the assumption of Gaussianity may play in this environment. In particular, for general non-Gaussian fields there is no guarantee that angular power spectra and related parameters can be consistently estimated, even at high multipoles - i.e., the Cosmic Variance does not decrease at high frequencies for general non-Gaussian models.
4 Discussion and directions for further research

This paper leaves many directions open for further research. We believe the results of the previous two sections point out a very strong connection between conditions for High Frequency Ergodicity (HFE) and High Frequency Gaussianity (HFG) for isotropic spherical random fields. It is natural to suggest that equivalence may hold for Gaussian subordinated fields of any order \( q \), or even more broadly for general Gaussian subordinated fields on homogeneous spaces of compact groups. Indeed, in this broader framework it is shown in [3] that independence of Fourier coefficients implies Gaussianity, which is the heuristic rationale behind our results here.

The connection between the HFE property can also be studied under a different environment than Gaussian subordination. Consider for instance the class of completely random spherical fields, which was recently introduced in [8, 9]. Following the definition therein, we shall say that a spherical random field is completely random if for each \( l \) we have that the vector \( a_l = (a_{l,1}, ..., a_{l,l}) \) is invariant with respect to the action of all matrices belonging to \( SU(2l + 1) \) and verifies \( a_{lm} = (-1)^m a_{lm} \). Because of this, the vector \( a_l \) is clearly uniformly distributed on the manifold of random diameter \( \sum |a_{lm}|^2 = \hat{C}_l \), or equivalently, introducing the \( (2l + 1) \) vector

\[
U_l = \frac{1}{\sqrt{2l + 1}} \left\{ \frac{\sqrt{2} \text{Re} a_{l1}}{\sqrt{\hat{C}_l}}, \frac{\sqrt{2} \text{Re} a_{l2}}{\sqrt{\hat{C}_l}}, ..., \frac{\sqrt{2} \text{Im} a_{l1}}{\sqrt{\hat{C}_l}}, ..., \frac{\sqrt{2} \text{Im} a_{ll}}{\sqrt{\hat{C}_l}} \right\}
\]

(29)

it holds that, for \( l \) large, it holds approximately that \( U_l \sim U(S^{2l}) \), i.e. \( U_l \) it is asymptotically distributed on the unit sphere of \( \mathbb{R}^{2l+1} \). Under these conditions, it is simple to show that \( HFE \Rightarrow HFG \), i.e.

\[
\left\{ \lim_{l \to \infty} E \left\{ \hat{C}_l - 1 \right\}^2 = 0 \right\} \Rightarrow \left\{ \frac{T_l(x)}{\sqrt{\text{Var}(T_l)}} \xrightarrow{law} N(0,1) , \text{ as } l \to \infty \right\} .
\]

Indeed, it is sufficient to note that, as before

\[
\frac{T_l(x)}{\sqrt{\text{Var}(T_l)}} = \frac{T_l}{\sqrt{(2l + 1)\hat{C}_l}} \xrightarrow{law} \sqrt{4\pi a_{l0}} \frac{1}{\sqrt{\hat{C}_l}} ,
\]

which we can write as

\[
a_{l0} \frac{1}{\sqrt{\hat{C}_l}} = a_{l0} \frac{1}{\sqrt{\hat{C}_l}} \frac{1}{\sqrt{\hat{C}_l}} = a_{l0} \frac{1}{\sqrt{\hat{C}_l}} .
\]

Now, as \( l \to \infty \)

\[
a_{l0} \frac{1}{\sqrt{\hat{C}_l}} \xrightarrow{law} N(0,1) ,
\]

because the left hand side can be viewed as the marginal distribution for a uniform law on a sphere of growing dimension; the latter is asymptotically Gaussian, as a consequence of Poincaré Lemma (see [10]). We do not investigate this issue more fully here, and we leave for future research the determination of general conditions such that (compare with (29))

\[
\text{the law of } U_l \text{ and } U(S^{2l}) \text{ are asymptotically close as } l \to \infty .
\]

(30)
Obviously, for all fields such that (30) holds (i.e. those that are asymptotically completely random, to mimic the terminology of [8, 9]), by the same argument as before we have that

\[
\left\{ \frac{\sqrt{C_l}}{C_l} \to \text{prob} \ 1 \right\} \Rightarrow \left\{ \frac{T_l}{\sqrt{(2l+1)C_l}} \overset{\text{law}}{\to} N(0,1) \right\} .
\]

To conclude this work, we wish to provide an example were the HFE and HFG property are indeed not equivalent. Consider the (anisotropic) field

\[
h(x) = \sum_{lm} \xi_{lm} Y_{lm}(x) , \quad \text{where} \quad \xi_{lm} = \begin{cases} \xi_l, & \text{for } m = 0 \\ 0, & \text{otherwise} \end{cases},
\]

and the random variables \(\xi_l\) verifies the assumption

\[
E\xi_l = 0, \quad \sum_l E\xi_l^2 < \infty \quad \text{and} \quad E\xi_l^4 < \infty .
\]

Note that, in the definition of \(h(x)\), the sum is not taken with respect to \(l\). The field can be made isotropic by taking a random rotation \(T(x) = h(gx)\), where \(g\) is a random, uniformly distributed element of \(SO(3)\). We have as usual \(T(x) = \sum_l \sum_{m=-l} a_{lm} Y_{lm}(x)\), where

\[
a_{lm} \overset{\text{law}}{=} \sum_{m'=-l} D_{m'm}^l(g) \xi_{lm'} \overset{\text{law}}{=} \sqrt{\frac{4\pi}{2l+1}} Y_{lm}(g) \xi_l ,
\]

and where \(\{D^l(g)\}\) denotes the well-known Wigner representation matrices for \(SO(3)\), and the first identity in law is discussed for instance in [8], [29]. Note that

\[
\sum_{m=-l} |a_{lm}|^2 = \frac{4\pi}{2l+1} \xi_l^2 \sum_{m=-l} |Y_{lm}(g)|^2 = \xi_l^2 ,
\]

as expected, because the sample angular power spectrum is invariant to rotations. Of course in this case we do not have ergodicity in general, i.e. it may happen that

\[
\frac{\sum_{m=-l} |a_{lm}|^2}{E\sum_{m=-l} |a_{lm}|^2} = \frac{\xi_l^2}{E\xi_l^2} \not\to 1
\]

and indeed for general sequences \(\{\xi_l\}\)

\[
E\left\{ \frac{\xi_l^2}{E\xi_l^2} - 1 \right\}^2 = E\left\{ \frac{\xi_l^2}{E\xi_l^2} \right\}^2 - 1 \neq 0 .
\]

However, in the special case where

\[
\xi_l = \begin{cases} e^{-l} \text{ with probability } \frac{1}{2} \\ -e^{-l} \text{ with probability } \frac{1}{2} \end{cases},
\]

we obtain easily that \(E\left\{ \frac{\xi_l^2}{E\xi_l^2} - 1 \right\}^2 = 0\), while asymptotic Gaussianity fails. Hence, we have constructed an example where the HFE property holds but the HFG property does not. Note that the support of the vector \(\{a_l\}\) is concentrated on a small subset of the sphere \(S^{2l}\); heuristically, this is what prevents Poincaré-like arguments to go through.
