(Dated: June 21, 2017)

In a recent Letter [T. Dornheim \textit{et al.}, Phys. Rev. Lett. \textbf{117}, 156403 (2016)], we presented the first quantum Monte Carlo (QMC) results for the warm dense electron gas in the thermodynamic limit. However, a complete parametrization of the exchange-correlation free energy with respect to density, temperature, and spin polarization remained out of reach due to the absence of (i) accurate QMC results below $\theta = k_B T / E_F = 0.5$ and (ii) of QMC results for spin polarizations different from the paramagnetic case. Here we overcome both remaining limitations. By closing the gap to the ground state and by performing extensive QMC simulations for different spin polarizations, we are able to obtain the first completely \textit{ab initio} exchange-correlation free energy functional; the accuracy achieved is an unprecedented $\sim 0.3\%$. This also allows us to quantify the accuracy and systematic errors of various previous approximate functionals.

The past decade has witnessed a rapid growth of interest in matter under extreme excitation or compression, as in laser-excited solids \cite{1} and inertial confinement fusion targets \cite{2,3,4,5}. Astrophysical examples such as white dwarf atmospheres and planet interiors \cite{6,7} provide further motivation. More down-to-earth examples appear in radiation damage cascades in the walls of fission or fusion reactors \cite{8}. Plasmonic catalysts use hot electrons created by the decay of plasmons in otherwise cold metallic nanoparticles to accelerate chemical reactions \cite{9,10}. Systems such as these, with thermal energies $k_B T$ comparable to the Fermi energy $E_F$ and densities comparable to or greater than those of ordinary solids, are said to be in the “warm dense matter” (WDM) regime \cite{11}. Because the degeneracy parameter $\Theta = k_B T / E_F$ is of order unity, neither the Pauli exclusion principle nor electronic excitations can be ignored and there are no small parameters in which to expand. This makes WDM challenging to understand theoretically.

Density functional theory (DFT) is by far the most important computational approach used to study molecules and solids at low temperatures \cite{12,13,14}, but relies for its success on the availability of good approximations to the unknown exchange-correlation (XC) energy functional. The development in the early eighties of accurate parametrizations \cite{15,16} of the ground-state local density approximation (LDA) to this functional played a decisive role in the ensuing rise of DFT.

DFT was generalized to finite temperatures \cite{17} soon after its invention, but applications to warm dense systems are a recent development. In part this is because the finite-temperature equivalent of the LDA is not known accurately. This Letter presents the first accurate and fully \textit{ab initio} calculation and parametrization of the XC free energy per electron, $f_{xc}$, as a functional of temperature, density and spin polarization, covering the entire range of conditions of interest in applications. The result is the natural generalization of Perdew and Zunger’s famous zero-temperature functional \cite{16}. It is key input not only to thermal DFT \cite{17,18,19}, but also for quantum hydrodynamics \cite{20,21} and the construction of equations of state for astrophysical objects \cite{22,23,24}.

The LDA is based on properties of the uniform electron gas (UEG), one of the seminal model systems in physics \cite{25}. Studies of the UEG led to key insights such as Fermi liquid theory \cite{26,27}, the quasi-particle picture of collective excitations \cite{28,29}, and the BCS theory of superconductivity \cite{30}. Accurate parametrizations of its ground-state properties \cite{15,16,31} were based on quantum Monte Carlo (QMC) simulations \cite{35,36,37} and have sparked many applications \cite{38,39,40} in addition to facilitating the remarkable successes of DFT \cite{12,13,14}.

QMC methods for the warm dense electron gas are much less developed, so the first parametrizations of $f_{xc}$ were based instead on uncontrolled approximations such as interpolations between known limits \cite{43}, semi-empirical quantum-classical mappings \cite{41,44}, and dielectric (linear response) methods \cite{45,46,47,48,49}. To overcome the severe limitations imposed by the fermion sign problem \cite{50,51}, the pioneering QMC simulations of the UEG by Brown \textit{et al.} \cite{52} used the approximate restricted path integral Monte Carlo (RPIMC) approach, in which the nodal structure of the density matrix is assumed. These data were used as input for several parametrizations of $f_{xc}$ \cite{46,53,54}, the most sophisticated being that of Karasiev \textit{et al.} (KSDT) \cite{53}, but were later shown to be inaccurate \cite{55}. The errors were $\sim 10\%$ near $r_s = 1$, where $r_s \equiv \bar{r}/a_B$, $\bar{r}$ is the radius of a sphere containing one electron on average, and $a_B$ is the Bohr radius. Unsurprisingly, the aforementioned models for $f_{xc}$ disagree substantially (cf. Fig. 1) in the WDM regime \cite{56}.

This unsatisfactory situation has sparked much recent work on finite-temperature fermionic QMC algorithms \cite{55,57,58,59,60,61,62,63,64,65}. By developing three complementary new
methods — configuration PIMC [55], permutation blocking PIMC [62, 63], and density matrix QMC [64, 65] — we are now able to overcome the sign problem in a broad parameter range without relying on a fixed-node approximation [66, 67]. In a recent Letter [61] we presented an improved procedure to extrapolate the QMC results to the thermodynamic limit and thereby obtained data for the unpolared UEG with an unprecedented accuracy of the order of 0.1%. At that time, however, the construction of a complete parametrization of $f_{xc}$ with respect to $r_s$, $\theta$ and $\xi = (N^s_\uparrow - N^s_\downarrow)/(N^s_\uparrow + N^s_\downarrow)$, where $N^s_\uparrow$ ($N^s_\downarrow$) is the number of spin-up (spin-down) electrons, was not possible. The fermion sign problem prevented us from performing QMC simulations for $0 < \theta < 0.5$. Further, we had no results for spin polarizations other than $\xi = 0$. The polarization dependence of $f_{xc}$ is used, for example, in DFT calculations in the local spin-density approximation, which require the evaluation of $f_{xc}$ at arbitrary $\xi$.

Here we solve these problems and present a new functional. Inspired by Tanaka and Ichimaru [48, 49] and the impressive accuracy of the Singwi-Tosi-Land-Sjölander (STLS) formalism [45, 46] in the warm dense regime [56], we bridge the gap between $\theta = 0$ and $\theta = 0.25$ by adding the (small) temperature dependence of the STLS interaction energy

$$\Delta_{\theta}^{STLS}(r_s, \theta, \xi) := v^{STLS}(r_s, \theta, \xi) - v^{STLS}(r_s, 0, \xi),$$

(1)

to the ground-state QMC interaction energy, which is known very accurately [39]. Second, we carry out extensive QMC simulations of the warm dense UEG for $\xi = 1/3, 0.6,$ and $1$ (179 data points in the ranges $0.1 \leq r_s \leq 20$ and $0.5 \leq \theta \leq 8$; see Table 3 in the Supplemental Material [68]). In combination with the results from Ref. [61], this allows us to construct the first completely $ab\ initio$ parametrization of the XC free energy, $f_{xc}(r_s, \theta, \xi)$, and to attain an unprecedented accuracy of $\sim 0.3\%$. The high quality of our new results is verified by various cross-checks and compared to the widely used parametrizations by Karasiev et al. (KSDT [53]), Perrot and Dharmawardana (PDW [44]), Ichimaru, Iyetomi, and Tanaka (IIT [48, 49]), and the recent improved dielectric approach by Tanaka [47].

**Parametrization of $f_{xc}$ for $\xi = 0$ and $\xi = 1.$** Following Refs. [48, 49] we obtain $f^1_{xc}$ from our QMC data for the electron-electron interaction energy $v^\xi(r_s, \theta)$ via the coupling-constant integration formula

$$f^1_{xc}(r_s, \theta) = \frac{1}{r_s^2} \int_0^{r_s} d\tau_s \tau_s v^\xi(\tau_s, \theta)$$

(2)

$$\Rightarrow v^\xi(r_s, \theta) = 2 f^1_{xc}(r_s, \theta) + r_s \left. \frac{\partial f^1_{xc}(r_s, \theta)}{\partial r_s} \right|_\theta$$

(3)

We employ Padé representations of $f^1_{xc}$ and $f^0_{xc}$ (see the Supplemental Material [68]) and fit the right-hand side of Eq. (3) to our combined data for $v^{1,0}$. To ensure the correct ground-state behaviour we note that $\lim_{\theta \to 0} f^1_{xc}(r_s, \theta) = c^\xi_{xc}(r_s, 0)$ and fit the zero-temperature...
limit of our Padé formula to the recent ground-state QMC results of Spink et al. [39]. In addition, the classical Debye-Hückel limit for large $\theta$ and the Hartree-Fock limit $f_{xc}^{HF}(r_s, \theta) = a(\theta)/r_s \equiv a^{HF}(\theta)/r_s$ [69] for $r_s \to 0$ are exactly incorporated.

The new results for $f_{xc}^{\xi}(r_s, \theta)$ are depicted in Fig. 1 (red dashed line) and compared to various approximations. While all curves exhibit a qualitatively similar behavior with respect to temperature, there are deviations of 5–12% for intermediate $\theta$ (bottom row). The IIT parametrization exhibits the smallest errors when $\xi = 0$, whereas, for $\xi = 1$, the PDW points are superior, although the IIT curve is of a similar quality. The recent parametrization by Tanaka (green) does not constitute an improvement compared to IIT. Finally, the KSDT curves are relatively accurate at low $\theta$ but systematically deviate for $\theta \gtrsim 0.5$, especially at high density ($r_s \lesssim 4$ [68]). The deviation of $\Delta f/f \sim 10\%$ at its maximum can be traced to an inappropriate finite-size correction of the QMC data by Brown et al. [52] (BCDC), see Ref. [61]. The deviations are even more severe for $\xi = 1$, in agreement with previous findings about the systematic bias in the RPIMC input data [66, 67] and with recent investigations [47, 49] of $f_{xc}$ itself. Also notice the pronounced bump of $f_{xc}^0$ occurring for large $r_s$ and low temperature (see inset in the middle panel), which induces an unphysical negative total entropy [70] in the KSDT fit.

Consider now our results for the interaction energy, shown as red rhombs and crosses in Fig. 1. We observe a smooth connection between our QMC data for $\theta \geq 0.5$ (crosses) and the temperature-corrected ground-state data (rhombs) in all three parts of the figure. The connection is equally smooth at all other densities investigated. The solid red line depicts the fit to $v^\xi$, Eq. (3). The Padé ansatz proves an excellent fitting function, able to reproduce the input data ($v^\xi$) for $\xi = 0$ ($\xi = 1$) with a mean and maximum deviation of 0.12% and 0.68% (0.17% and 0.63%) [71].

To further illustrate the high quality of our XC functional and to verify the accuracy of the applied temperature correction at low $\theta$, we carried out extensive new QMC simulations for the XC internal energy per particle, $e_{xc}$, for $r_s = 1$ and $\xi = 1$, over the entire range of temperatures down to $\theta = 0.0625$ (see Ref. [68] for details). The finite-size-corrected data are compared to $e_{xc}$ reconstructed from our parametrization of $f_{xc}^{\xi}(r_s, \theta)$ via [53]

$$e_{xc}^{\xi}(r_s, \theta) = f_{xc}^{\xi}(r_s, \theta) - \theta \frac{\partial f_{xc}^{\xi}(r_s, \theta)}{\partial \theta} \Big|_{r_s}.$$  

This allows us not only to gauge the accuracy of $f_{xc}$ itself but also its temperature derivative, which is directly linked to the XC entropy. The results are presented in Fig. 2 and demonstrate excellent agreement between our parametrization (red solid line) and the independent new QMC data (red dots) over the entire range of $\theta$. Since the new data for $e_{xc}$ were not used for our fit this constitutes strong confirmation of the accuracy of the low-temperature results obtained by using STLS theory to correct the $T=0$ XC energy, and demonstrates the consistency of our parametrization. Other functionals are much less consistent (see blue symbols and line) [71, 72].

**Spin interpolation.** To obtain an accurate parametrization of $f_{xc}$ at arbitrary spin polarization $0 \leq \xi \leq 1$ we employ the ansatz [44]

$$f_{xc}(r_s, \theta, \xi) = f_{xc}^0(r_s, \theta^0) + \left[ f_{xc}^1(r_s, \theta^0) \cdot 2^{-2/3} \right] - f_{xc}^0(r_s, \theta^0) \right] \Phi(r_s, \theta^0, \xi),$$  

with $\theta^0 = \theta(1+\xi)^{2/3}$. The form and fitting procedure used for the interpolation function $\Phi(r_s, \theta^0, \xi)$ are described in the Supplemental Material [68]. Interestingly, we find that a single fitting parameter is sufficient to capture the full temperature dependence of $\Phi$ for all values of $\xi$, with a mean and maximum deviation from the QMC data at intermediate $\xi$ of 0.15% and 0.8%.

Note that this is the first time that $\Phi(r_s, \theta, \xi)$ has been obtained accurately from *ab initio* data. A comparison of the $\xi$ dependence of $f_{xc}$ with various earlier parametrizations is depicted in Fig. 3. The IIT and Tanaka curves, which utilize a different functional form for the spin interpolation [73], exhibit the largest deviations at intermediate temperatures. Our spin-interpolation function has the same form [68] as that employed in the KSDT parametrization. However, due to the absence of RPIMC data for intermediate $\xi$, KSDT used the classical mapping of Ref. [44] to determine the coefficients of $\Phi$. Overall, the KSDT fit is closest to our parametrization at low $\theta$, while for $\theta > 1$ the IIT curve is more accurate. Nevertheless, we conclude that no previous model satisfactorily captures the $\xi$ dependence uncovered by our data.

**Summary and discussion.** In summary, we have presented the first accurate and fully *ab initio* XC free energy...
functional for the UEG at WDM conditions, achieving an unprecedented precision of \( \frac{\Delta f_{xc}}{f_{xc}} \sim 0.3\% \). To cover the entire parameter range relevant to experiments, we carried out extensive QMC simulations for multiple spin polarizations at 0.1 \( \leq r_s \leq 20 \) and 0.5 \( \leq \theta \leq 8 \). In addition, we obtained accurate data for 0.0625 \( \leq \theta \leq 0.25 \) by combining ground-state QMC results with a small STLS-based temperature correction. All of our results are tabulated in the Supplemental Material [68] and provide benchmarks for the development of new theories and simulation schemes as well as for the improvement of existing models.

The first step in our construction of the complete XC functional, \( f_{xc}(r_s, \theta, \xi) \), was to parametrize the completely polarized and unpolarized cases. This was achieved by fitting the right-hand side of Eq. (3) to our new data for the interaction energy, \( v^z \), for \( \xi = 0 \) and \( \xi = 1 \). The resulting parametrization reproduces the input data with a mean deviation of 0.17%, better by at least an order of magnitude than the KSDT fit. As an additional test of our parametrization, we performed independent QMC calculations of \( e_{xc} \) (the XC energy per electron) for a wide range of values of \( \theta \) down to \( \theta = 0.0625 \) and compared the results with values of \( e_{xc} \) calculated using our functional for \( f_{xc} \). The striking agreement obtained constitutes strong evidence for the accuracy of the STLS-based corrections used at low temperature and for the consistency of our work in general.

Equipped with our new XC functional, we have also investigated the systematic errors of previous parametrizations. Overall, the functional by Ichimaru et al. [48, 49] deviates the least from our results, although at \( \xi = 1 \) the classical mapping results by Perrot and Dharma-wardana [44] are similarly accurate. The KSDT parametrization exhibits large deviations exceeding 10% at high temperature and density. At low temperatures, however, it performs surprisingly well, in part because it does not reproduce the systematic biases in the RPIMC data on which it was based.

The construction of the first ab initio spin-interpolation function \( \Phi(r_s, \theta, \xi) \) at WDM conditions constitutes the capstone of this work. Surprisingly, we find that a one-parameter fit is sufficient to capture the whole temperature dependence of the spin-interpolation function. Further, we show that no previously suggested spin interpolation gives the correct \( \xi \) dependence throughout the WDM regime.

We are confident that our extensive QMC data set and accurate parametrization of the thermodynamic functions of the warm dense electron gas will be useful in many applications. Given recent developments in thermal Kohn-Sham DFT [74, 75], time-dependent Kohn-Sham DFT [76] and orbital-free DFT [77, 78], our parametrization of \( f_{xc} \) is directly applicable for calculations in the local spin-density approximation. Furthermore, our functional can be used as a basis for gradient expansions [79, 80], or as a benchmark for nonlocal functionals based on the fluctuation-dissipation theorem [81]. In addition, it can be straightforwardly incorporated into widely used approximations in quantum hydrodynamics [20, 21] or for the equations of state of astrophysical objects [22–24]. Finally, our XC functional should help resolve several exciting and controversial issues in warm dense matter physics, such as the existence and locations of the phase transitions in warm dense hydrogen [82–84] or details of hydrogen-helium demixing [85].

Computational implementations of our XC functional (in FORTRAN, C++, and Python) are available online [86].

[71] In contrast, the KSDT interaction energy (solid blue line) exhibits severe deviations to the corresponding BCDC data (blue dots). This indicates that using the systematically biased RPIMC data as input for a parameterization of fxc does not allow to consistently recover other quantities (see also the discussion of Fig. 2).

[72] Note that the KSDT parametrization is the result of a direct fit to the RPIMC data for fxc but only reproduces these data for θ ≥ 1 and strongly deviates below (the KSDT fit exhibits a mean and maximum deviation to the underlying RPIMC data of 1.2% and 7.8% for ξ = 1).
