Linear Precoder Design for MIMO Interference Channels with Finite-Alphabet Signaling

Yongpeng Wu, Student Member, IEEE, Chengshan Xiao, Fellow, IEEE, Xiqi Gao, Senior Member, IEEE, John D. Matyjas, Member, IEEE, and Zhi Ding, Fellow, IEEE

Abstract—This paper investigates the linear precoder design for $K$-user interference channels of multiple-input multiple-output (MIMO) transceivers under finite alphabet inputs. We first obtain general explicit expressions of the achievable rate for users in the MIMO interference channel systems. We study optimal transmission strategies in both low and high signal-to-noise ratio (SNR) regions. Given finite alphabet inputs, we show that a simple power allocation design achieves optimal performance at high SNR whereas the well-known interference alignment technique for Gaussian inputs only utilizes a partial interference-free signal space for transmission and leads to a constant rate loss when applied naively to finite-alphabet inputs. Moreover, we establish necessary conditions for the linear precoder design to achieve weighted sum-rate maximization. We also present an efficient iterative algorithm for determining precoding matrices of all the users. Our numerical results demonstrate that the proposed iterative algorithm achieves considerably higher sum-rate under practical QAM inputs than other known methods.

Index Terms—Finite alphabet, interference channel, linear precoding, MIMO

I. INTRODUCTION

The recent decade has witnessed the widespread application of multiple-input multiple-output (MIMO) wireless communication systems because of their superb spectral efficiency and link reliability [1–3]. However, potential benefits of MIMO systems are often hampered by the omnipresent interference in typical scenarios of wireless networks [4–7]. For this reason, considerable research interests have focused on MIMO interference channels recently. Unlike the general tendency to assume Gaussian signal inputs in such works, our paper here investigates linear precoding of $K$-user MIMO interference channel systems for finite alphabet input signals.

Although there have been substantial progresses in information-theoretical analysis of Gaussian interference channels in some special cases [8–10], the fundamental limits of the interference channels still remain unresolved in general [11]. A more recent signal multiplexing approach, called interference alignment (IA), has shown that the degrees of freedom (DOF) of the interference channels may be achieved in high signal-to-noise ratio (SNR) region [12]. The IA concept has been extended to MIMO interference channel systems [13, 14]. Furthermore, linear precoding designs maximizing the weighted sum-rate (WSR) performance of the MIMO interference channel systems in moderate SNR region can be found in [15]. Nevertheless, the aforementioned information-theoretic works attempt to optimize the performance of interference channel systems by relying on the convenience of Gaussian input assumption. Despite the information-theoretic optimality of Gaussian inputs, practical communication systems rarely transmit Gaussian signals. It is well known that practical signals usually are generated from finite discrete constellation sets such as phase-shift keying (PSK), pulse-amplitude modulation (PAM), or quadrature amplitude modulation (QAM). MIMO precoders designed for Gaussian input assumption may often lead to a considerable performance loss when applied haphazardly to practical systems with finite alphabet signaling. We take point-to-point case as an example. For QPSK modulation, as illustrated in Figure 2 and Figure 4 in [16], the performance gaps between the finite alphabet input design and the Gaussian input design are more than 15 dB at 0.75 coding rate.

Thus, transmitter designs for optimizing the constellation-constrained mutual information appear more plausible in practice. Such problems in the context of point-to-point communication scenarios [16–19] have been recently studied. Precoding designs in multiple access channels, broadcast channels, relay channels, and wiretap channels have also appeared [20–25]. In [26], a transmit precoding design for two user single-input single-output (SISO) strong interference channels with finite
alphabet inputs was proposed. It was suggested in [26] to design the precoders by an exhaust search for the optimal rotation of the signal constellation at the second user side.

To the best of our knowledge, not much has been published on the MIMO interference channel systems under finite alphabet constraints. This paper considers the linear precoder designs to maximize the WSR of the MIMO interference channel systems under finite alphabet constraints of channel inputs. Our results differ significantly from previous finite alphabet research work since the existing results on the MIMO multiuser systems with finite alphabet inputs [21, 23] cannot be directly applied to the MIMO interference channel systems. Besides, new insights of the precoding designs over MIMO interference channels in asymptotic SNR regions are revealed. Moreover, a novel receiver structure exploiting the finite discrete constellation set is provided. The specific contributions of this paper can be summarized as follows. Based on the mutual information between the channel input and output, we first derive an exact expressions of the achievable rate of each user in the MIMO interference channel systems with finite alphabet inputs. The characterization is applicable to $K-$users with generic antenna configurations. We then find a near-optimal transmission strategy in low SNR region, where each user performs beamforming in the strongest eigenmode of its channel matrix. This transmission design coincides with the low-SNR optimal precoding policy in the point-to-point MIMO scenarios and also for Gaussian inputs. At high SNR, however, the precoding design with finite alphabet inputs is significantly different from that with Gaussian inputs. For Gaussian input, the optimal IA technique [13, 15] constructs the precoder of each transmitter by properly aligning interference of each receiver to a partial signal space. The remaining interference-free space is utilized for signal transmissions. However, when replaced with finite alphabet inputs, the IA technique may lead to a serious performance loss. This is because finite alphabet inputs lead to saturated mutual information. Thus, allocating more power to signals of high SNR beyond saturation does not further increase mutual information. This means that using only a partial signal space for transmitting signals will result in a constant sum-rate loss in finite alphabet input scenarios. For example, if each transmitter has $N_T$ antenna and each receiver has $N_R$ antenna, we prove that the IA technique will result in $(\eta + 1)^{-1} \sum_{j=1}^{K} \log_2 M_j$ b/s/Hz sum-rate loss at high SNR, where $M_j$ denotes the size of the modulation set and $\eta$ depends on the ratio of $N_R$ and $N_T$.

As a consequence, instead of the IA, we propose a novel and concise power allocation scheme exploiting the full signal space for signal transmission at high SNR. Our scheme applies to arbitrary number of users and arbitrary antenna configurations. We prove that the proposed scheme can effectively combat interference and achieve the saturated sum-rate $\sum_{j=1}^{K} \log_2 M_j$ b/s/Hz at high SNR. More generally, due to the non-convexity of the WSR with respect to the precoding matrices, we derive a set of necessary conditions for the optimal precoding matrices through Karush-Kuhn-Tucker (KKT) analysis and further propose an iterative algorithm using gradient descent and backtracking line search for finding the optimal precoders. Numerical results show that the proposed algorithm converges within several steps and achieves significant WSR gains over the conventional iterative designs. In addition to WSR, the coded bit error rate (BER) of the MIMO interference channel systems is another important performance evaluation criterion in practice. To further examine the robust performance of the proposed design, we present iterative transceiver systems for the MIMO interference channels by deploying low-density parity-check (LDPC) encoders and the proposed precoders at the transmitters, and the soft maximum a posteriori (MAP) multiuser detectors and LDPC decoders at the receivers. Simulations show that the proposed precoding design achieves substantial coded BER improvement through the iterative decoding and detection operations. Furthermore, recognizing interference signals as finite alphabet inputs rather than colored Gaussian noise, we designed a novel detector structure that provides additional coded BER gains.

The following notations are adopted throughout the paper: Column vectors are represented by lower-case bold-face letters, and matrices are represented using upper-case bold-face letters. Superscripts $(\cdot)^T$, $(\cdot)^*$, and $(\cdot)^H$ represent the matrix/vector transpose, conjugate, and conjugate-transpose operations, respectively. We let $||\cdot||$ and $||X||_F$ denote the Euclidean norm of vector $\mathbf{x}$ and the Frobenius norm of matrix $\mathbf{X}$, respectively. $\mathbb{C}$ denotes the complex field, $\mathbb{C}^{M \times M}$ denotes an $M \times M$ identity matrix (sometimes without using subscript $M$) and $E_V$ represents the expectation of random variable (scalar, vector, or matrix) $V$.

II. SYSTEM MODEL AND EXISTING RESULTS OF MIMO INTERFERENCE CHANNEL WITH GAUSSIAN INPUTS

We consider a $K$-user interference channel system in which each transmitter has dedicated information for its intended receiver and generates co-channel interference to other receivers as illustrated in Figure 1. Suppose the $i$-th transmitter has $N_i$ antennas and the $j$-th receiver has $N_j$ antennas for every $i, j = 1, 2, \ldots, K$. In addition, we assume no collaboration among transmitters or receivers. Then, the received signal $\mathbf{y}_j \in \mathbb{C}^{N_j \times 1}$ observed at the $j$-th receiver can be described as

$$\mathbf{y}_j = \mathbf{H}_{jj}\mathbf{G}_j\mathbf{x}_j + \sum_{i=1, i \neq j}^{K}\mathbf{H}_{ji}\mathbf{G}_i\mathbf{x}_i + \mathbf{n}_j, \quad j = 1, 2, \cdots, K \quad (1)$$

where $\mathbf{x}_i \in \mathbb{C}^{N_i \times 1}$ and $\mathbf{n}_j \in \mathbb{C}^{N_j \times 1}$ denote the zero-mean transmitted information vector and noise vector for the $j$-th user with covariance matrices $\mathbf{I}$ and $\sigma^2 \mathbf{I}$, respectively. Also, $\mathbf{G}_j$ represents the linear precoding matrix for the $j$-th user, and $\mathbf{H}_{ji} \in \mathbb{C}^{N_j \times N_i}$ stands for the channel response matrix between the $i$-th transmitter and the $j$-th receiver, which is normalized as $\text{tr}(\mathbf{H}_{ji}\mathbf{H}^H_{ji}) = N_{ji}$. Here we make the common assumption (e.g., as in [12, 15], among others)
that the channel state information is globally available, i.e., each transmitter has access to perfect channel knowledge of all users. Moreover, we assume the precoding matrix does not increase the transmission power. Henceforth, we have the power constraint
\[ \text{tr} \left( E \left[ \mathbf{G}_j \mathbf{x}_j \mathbf{x}_j^H \mathbf{G}_j^H \right] \right) = \text{tr} \left( \mathbf{G}_j \mathbf{G}_j^H \right) \leq P_j, \quad j = 1, 2, \ldots, K \]
where \( P_j \) denotes the maximum average transmitted power at the \( j \)-th transmitter.

![Figure 1: K-user interference channels with multiple antennas.](image)

We now briefly review the existing linear precoding design in the MIMO interference channel systems based on Gaussian input assumption. When \( \mathbf{x}_j \sim \mathcal{CN}(0, \mathbf{I}_{N_j}) \), \( j = 1, 2, \ldots, K \), the achievable rate for the \( j \)-th user is given by [15]
\[ R_j = \log_2 \det \left( \sigma^2 \mathbf{I} + \sum_{i=1}^K \mathbf{H}_{ji} \mathbf{G}_i \mathbf{G}_i^H \mathbf{H}_{ji}^H \right) - \log_2 \det \left( \sigma^2 \mathbf{I} + \sum_{i=1}^K \mathbf{H}_{ji} \mathbf{G}_i \mathbf{G}_i^H \mathbf{H}_{ji}^H \right). \]
Therefore, the optimum precoding matrices for maximizing the WSR can be expressed as
\[ \{ \mathbf{G}_1^*, \mathbf{G}_2^*, \ldots, \mathbf{G}_K^* \} = \arg \max_{\mathbf{G}_1, \mathbf{G}_2, \ldots, \mathbf{G}_K} R_{\text{sum}} \]
where
\[ R_{\text{sum}} = \sum_{j=1}^K \mu_j \log_2 \det \left( \sigma^2 \mathbf{I} + \sum_{i=1}^K \mathbf{H}_{ji} \mathbf{G}_i \mathbf{G}_i^H \mathbf{H}_{ji}^H \right) - \sum_{j=1}^K \mu_j \log_2 \det \left( \sigma^2 \mathbf{I} + \sum_{i=1,i \neq j}^K \mathbf{H}_{ji} \mathbf{G}_i \mathbf{G}_i^H \mathbf{H}_{ji}^H \right) \]
and \( \mu_j \) denotes the weighting factor of the \( j \)-th user, \( j = 1, 2, \ldots, K \), where \( \sum_{j=1}^K \mu_j = K \). Then, by exploiting the matrix derivative results in [27], along with the complex matrix differentiation conclusions in [28], we can calculate the gradient of the WSR with respect to \( \mathbf{G}_k \) as
\[ \nabla_{\mathbf{G}_k} R_{\text{sum}} = \log_2 c \left\{ \begin{array}{l} \mu_j \mathbf{H}_{jk}^H \left( \sigma^2 \mathbf{I} + \sum_{i=1}^K \mathbf{H}_{ji} \mathbf{G}_i \mathbf{G}_i^H \mathbf{H}_{ji}^H \right)^{-1} \mathbf{H}_{jk} \mathbf{G}_k \\
- \mu_j \mathbf{H}_{jk}^H \left( \sigma^2 \mathbf{I} + \sum_{i=1,i \neq j}^K \mathbf{H}_{ji} \mathbf{G}_i \mathbf{G}_i^H \mathbf{H}_{ji}^H \right)^{-1} \mathbf{H}_{jk} \mathbf{G}_k \end{array} \right. \]
where \( k = 1, 2, \ldots, K \).

Given the derived gradient expression, an iterative algorithm was proposed in [15] to solve the optimal precoders \( \{ \mathbf{G}_1^*, \mathbf{G}_2^*, \ldots, \mathbf{G}_K^* \} \).

### III. Linear Precoding Design With Finite-Alphabet Inputs

In practical communications, \( \mathbf{x}_k \) is generated as equi-probably from discrete constellations (e.g. \( M \)-ary PSK, PAM, or QAM). In this section, we discuss the linear precoding design to maximize the WSR under the practical finite alphabet constraints.

#### A. Achievable Rate of Each User

We assume \( \mathbf{x}_j \) comes from the constellation set \( S_j \) with cardinality \( Q_j \), and define \( M_j = Q_j^{N_j}, \quad j = 1, 2, \ldots, K \). Define \( I_j \) as the \( N_j \) product space of \( Q_j \) for the \( j \)-th user and let \( \mathbf{x}_{j,p} \) denote the \( p \)-th element in constellation set \( I_j \), where \( p = 1, 2, \ldots, M_j, j = 1, 2, \ldots, K \). Then, we have the following results.

**Proposition 1:** Let the channel noise \( \mathbf{n} \sim \mathcal{CN}(0, \sigma^2 \mathbf{I}) \). When the discrete input data \( \mathbf{x}_j \) of the \( j \)-th user in the MIMO interference channel model (1) is independent and uniformly distributed over constellation set \( S_j \), the achievable rate for the \( j \)-th user \( (j = 1, 2, \ldots, K) \) can be expressed as
\[ R_{\text{sum}} = \log_2 M_j - \frac{1}{\prod_{m=1}^K M_m} \sum_{m_1=1}^{M_1} \sum_{m_2=1}^{M_2} \cdots \sum_{m_K=1}^{M_K} E_n \log_2 \left( \frac{H_{1,j}(m_1,m_2,\ldots,m_K,\mathbf{n})}{H_{2,j}(m_1,\ldots,m_{j-1},m_{j+1},\ldots,m_K,\mathbf{n})} \right) \]
where
\[ H_{1,j}(m_1,m_2,\ldots,m_K,\mathbf{n}) = \sum_{n_1=1}^{M_1} \sum_{n_2=1}^{M_2} \cdots \sum_{n_K=1}^{M_K} \exp \left( -\frac{\left\| \sum_{k=1}^K \mathbf{H}_{ji} \mathbf{G}_k \mathbf{x}_{m_k} - \mathbf{x}_{n_k} \right\|^2}{\sigma^2} \right) \]
\[ H_{2,j}(m_1,\ldots,m_{j-1},m_{j+1},\ldots,m_K,\mathbf{n}) = \sum_{n_1=1}^{M_1} \sum_{n_2=1}^{M_2} \cdots \sum_{n_{j-1}=1}^{M_{j-1}} \sum_{n_{j+1}=1}^{M_{j+1}} \cdots \sum_{n_K=1}^{M_K} \exp \left( -\frac{\left\| \sum_{k=1}^K \mathbf{H}_{ji} \mathbf{G}_k \mathbf{x}_{m_k} - \mathbf{x}_{n_k} \right\|^2}{\sigma^2} \right) \]

**Proof:** See Appendix A.

---

We note that the derived gradient form here is a little different from [15, Eq. (38)]. This is because we rewrite the WSR expression in [15, Eq. (35)] only for notation simplicity. Mathematically, they are equivalent.
\[ R_{1, \text{finite}} = \log_2 M_1 + \frac{1}{M_2} \sum_{m_2=1}^{M_2} E_n \log_2 \sum_{n_2=1}^{M_2} \exp \left( -\frac{\| \mathbf{H}_{12} \mathbf{G}_{2}(\mathbf{x}_{2,m_2} - \mathbf{x}_{2,n_2}) + \mathbf{n} \|^2}{\sigma^2} \right) \]
\[ - \frac{1}{M_1 M_2} \sum_{m_1=1}^{M_1} \sum_{m_2=1}^{M_2} E_n \log_2 \sum_{n_1=1}^{M_1} \sum_{n_2=1}^{M_2} \exp \left( -\frac{\| \sum_{i=1}^{K} \mathbf{H}_{1i} \mathbf{G}_{i}(\mathbf{x}_{i,m_1} - \mathbf{x}_{i,n_1}) + \mathbf{n} \|^2}{\sigma^2} \right) \]
\[ R_{2, \text{finite}} = \log_2 M_2 + \frac{1}{M_1} \sum_{m_1=1}^{M_1} E_n \log_2 \sum_{n_1=1}^{M_1} \exp \left( -\frac{\| \mathbf{H}_{21} \mathbf{G}_{1}(\mathbf{x}_{1,m_1} - \mathbf{x}_{1,n_1}) + \mathbf{n} \|^2}{\sigma^2} \right) \]
\[ - \frac{1}{M_1 M_2} \sum_{m_1=1}^{M_1} \sum_{m_2=1}^{M_2} E_n \log_2 \sum_{n_2=1}^{M_2} \sum_{n_1=1}^{M_1} \exp \left( -\frac{\| \sum_{l=1}^{K} \mathbf{H}_{2i} \mathbf{G}_{i}(\mathbf{x}_{i,n_1} - \mathbf{x}_{i,n_1}) + \mathbf{n} \|^2}{\sigma^2} \right). \]

The results in Proposition 1 are general for an arbitrary number of users and arbitrary antenna configurations. For two users, the achievable rate of \( R_1 \) and \( R_2 \) can be simplified as in (10) and (11) at the top of the next page.

In practice, a great amount of wireless systems may work at low power, especially for the wireless units operated by batteries. For instance, it was reported in [29, 30] that for batteries. For instance, it was reported in [29, 30] that the geographical locations undergo receiver SNR levels below 0 dB. In addition, a key objective in future digital communication systems, the energy-efficient requirement necessitates the operation in low SNR region. It was indicated in [31] that the energy efficiency enhances as one operates in low SNR region, and the minimum bit energy is achieved as SNR vanishes. Therefore, next we present closed form expressions for a near-optimal transmit strategy in low SNR region.

**Proposition 2:** For the interference channel model (1), a near-optimal transmit precoding design in low SNR region \((\sigma^2 \to \infty)\) is given by

\[ \mathbf{G}_j = \sqrt{\mathbf{P}_j} [\mathbf{v}_{\max,j} \ 0], \quad j = 1, 2, \cdots, K \]  

(12)

where \( \mathbf{v}_{\max,j} \) is the eigenvector corresponds to the largest eigenvalue of the matrix \( \mathbf{H}_{jj}^\dagger \mathbf{H}_{jj} \).

**Proof:** See Appendix B.

Proposition 2 suggests that for low SNR, each user should perform beamforming along its own channel response matrix while ignoring the impact of interference from other users. This is actually in agreement with intuition, since, when the SNR is low, interferences become negligible such that each user can design its transmission precoder accordingly to its own channel state information. Thus, the precoding structure in (12) directly yields the low-SNR optimal precoding policy in point-to-point \((K = 1)\) MIMO scenarios [3, 17]. In addition, theoretically, we have the following corollary.

**Corollary 1:** For the interference channel model (1) with Gaussian inputs, the linear precoding design in Proposition 2 is optimum in low SNR region.

**Proof:** See Appendix C.

Here we define \( \mathbf{a}_{i,j,m_i,n_i} = \mathbf{H}_{ji}(\mathbf{x}_{i,m_i} - \mathbf{x}_{i,n_i}), \ i = 1, 2, \cdots, K; \ j = 1, 2, \cdots, K; \ m_i = 1, 2, \cdots, M_i; \ n_i = 1, 2, \cdots, M_i \). Let \( \mathbf{a}_{i,j,m_i,n_i,t} \) be the \( t \)-th element of vector \( \mathbf{a}_{i,j,m_i,n_i} \), \( t = 1, 2, \cdots, N_r \). For a fixed \( i \), we assume there are \( T_i \) distinct \( |\mathbf{a}_{i,j,m_i,n_i,t}| > 0 \), which we denote as \( b_{i,l}, l = 1, 2, \cdots, T_i \). We define

\[ \omega_{i,\min} = \min \{ b_{i,l} \}, \quad l = 1, 2, \cdots, T_i \]
\[ \omega_{i,\max} = \max \{ b_{i,l} \}, \quad l = 1, 2, \cdots, T_i. \]

Next, we give an optimal transmit precoding in high SNR region as follows:

**Proposition 3:** For the interference channel model (1), a transmit precoding design achieving optimum performance in high SNR region \((\sigma^2 \to 0)\) is given by

\[ \mathbf{G}_i = \sqrt{\frac{\mathbf{P}_i}{N_{t_i}}} \mathbf{I}_{N_{r_i}}, \quad i = 1, 2, \cdots, K \]  

(15)

where \( \mathbf{P}_i = \begin{cases} 1 & \text{if } \omega_{i,\min} > 0, \ i = 1, 2, \cdots, K \\ 0 & \text{otherwise} \end{cases} \) \( i = 1, 2, \cdots, K \) satisfy the following conditions

\[ \sqrt{\frac{\mathbf{P}_i}{N_{t_i}}} \omega_{i,\min} > \sum_{q=1}^{K} \sqrt{\frac{\mathbf{P}_q}{N_{t_q}}} \omega_{q,\max}, \quad i = 1, 2, \cdots, K. \]

(16)

Based on the precoding design in (15), the sum-rate of all the receivers in model (1) at high SNR is given by

\[ R_{\text{sum}} = \sum_{j=1}^{K} \log_2 M_j \]  

(17)

**Proof:** See Appendix D.

Proposition 3 implies that for finite alphabet input signals, a proper power allocation scheme can effectively eliminate the effect of interference caused by other users’ transmission data with generic antenna configurations. Equation (17) indicates that the sum-rate achieved by the proposed scheme saturates at the bound rate of the entire signal space in high SNR region. The IA technique [13, 15] in contrast, which only utilizes a partial interference-free signal space for transmission, will

\[ \text{It should be noted that the result in Proposition 3 does not simply state an intuitive fact. To elaborate on this, we consider a simple example of 2-user SISO interference channels. Assume } h_{11} = h_{12} = 0.5, \ g_1 = g_2 = 1, \ \text{and BPSK modulation is employed. When SNR is high (the impact of the noise vanishes), if the received signal at the receiver 1 is } y_1 = 0, \ \text{then the receiver 1 is unable to decode whether the transmitted signal } x_1 = +1 \text{ or } -1. \ \text{It is because the probabilities of } x_1 = 1, x_2 = -1 \text{ and } x_1 = -1, x_2 = 1 \ \text{are equally the same. This implies that for finite alphabet input signals, even when the constellation size at each transmitter is kept fixed as SNR grows, each receiver may still not be able to decode all the messages from all the transmitters correctly. As a consequence, proper transmit design as in Proposition 3 is required to achieve the optimal performance in high SNR region.} \]
result in a serious performance degradation at high SNR. Specifically, we consider an example where \( N_{t_j} = N_T, j = 1, 2, \cdots, K \) and \( N_{r_j} = N_R, j = 1, 2, \cdots, K \). We define \( \eta = \frac{\min(N_T, N_R)}{\max(N_T, N_R)} \). To characterize the performance loss, we have the following corollary.

**Corollary 2:** Consider the case where \( N_{t_j} = N_T, j = 1, 2, \cdots, K \) and \( N_{r_j} = N_R, j = 1, 2, \cdots, K \). If \( K > \eta \), the average sum-rate per channel use in model (1) via IA technique at high SNR is given by

\[
P_{\text{sum,IA}}^\infty = \frac{\eta}{\eta + 1} \sum_{j=1}^{K} \log_2 M_j. \tag{18}
\]

**Proof:** See Appendix E.

Corollary 2 indicates that, for MIMO interference channel with finite alphabet inputs, a constant performance loss of the IA technique at high SNR is given by

\[
\eta \frac{\sum_{j=1}^{K} \log_2 M_j}{\eta + 1}
\]

**B. Necessary Conditions of the Optimum Precoding Matrices**

Based on Proposition 1, we consider the following WSR optimization problem

\[
R_{\text{wsum, finite}}(G_1, G_2, \cdots, G_K) = \max_{G_1, G_2, \cdots, G_K} \frac{1}{2} \sum_{j=1}^{K} \mu_j R_{j, \text{finite}}(G_1, G_2, \cdots, G_K) \tag{19}
\]

subject to \( \text{tr}(G_j^H G_j) \leq P_j, j = 1, 2, \cdots, K \). \tag{20}

In general, the WSR objective function \( R_{\text{wsum, finite}}(G_1, G_2, \cdots, G_K) \) in (19) is not concave with respect to precoding matrices \( \{G_1, G_2, \cdots, G_K\} \). Thus, a set of necessary conditions for this optimization problem are determined, as given in the following proposition.

**Proposition 4:** The optimal precoding matrices for the WSR maximization problem in (19) and (20), satisfies the following conditions

\[
\kappa_j G_j = \frac{\log_2 e}{\sigma^2} \left( \sum_{i=1}^{K} \mu_i H_{ii}^H T_{1, i, j} - \sum_{i=1, i \neq j}^{K} \mu_i H_{ij}^H T_{2, i, j} \right), \quad j = 1, 2, \cdots, K \tag{21}
\]

\[
\kappa_j \left( \text{tr}(G_j^H G_j) - P_j \right) = 0, \quad j = 1, 2, \cdots, K \tag{22}
\]

\[
\text{tr}(G_j^H G_j) - P_j \leq 0, \quad j = 1, 2, \cdots, K \tag{23}
\]

\[
\kappa_j \geq 0, \quad j = 1, 2, \cdots, K \tag{24}
\]

where the \( N_{r_j} \times N_{t_j} \) matrices \( T_{1, i, j} \) and \( T_{2, i, j} \) are given as in (25) and (26) at the top of the next page, where \( d_{j, m_j, n_j} = x_{j, m_j} - x_{n_j, n_j} \). \tag{26}

**Proof:** See Appendix F.

\[
C. \text{ Iterative Algorithm For Weighted Sum Rate Maximization}
\]

From (21), we observe that the optimal precoding matrices of different users are mutually dependent. For this reason, here we propose a numerical algorithm to search for the joint optimization of \( \{G_1, G_2, \cdots, G_K\} \). We adopt a commonly used suboptimal approach in dealing with multi-variables optimization problems, which iteratively optimizes one variable at a time with others fixed [32]. During each iteration, gradient descent method updates the precoding matrix for a single user. Specifically, we generate the gradient descent directions by computing the partial mutual information derivatives of the WSR (19) with respect to \( G_j, j = 1, 2, \cdots, K \), which are given by the right-hand-side of (21). The backtracking line search algorithm is incorporated for fast convergence, where the two related parameters \( \alpha \) and \( \beta \) are within \( (0, 0.5) \) and \( \beta \in (0, 1) \) [33]. Moreover, if the obtained solution satisfies \( \text{tr} \{G_j, G_j^H\} > P_j \), we can project \( G_j \) to the feasible set via a normalization step:

\[
G_j := \sqrt{\text{tr}(G_j^H G_j)} / \sqrt{\text{tr}(G_j^H G_j)} \tag{34}
\]

**Algorithm 1:** Gradient descent to maximize the WSR over \( G_1, G_2, \cdots, G_K \).

1) Initialize \( G_j^{(0)} \) with \( \left( G_j^{(0)}^H G_j^{(0)} \right) = P_j, j = 1, 2, \cdots, K \). Set \( n = 0 \).
2) Compute \( R_{\text{wsum, finite}}(G_1^{(n)}, G_2^{(n)}, \cdots, G_K^{(n)}), T_{1, i, j}^{(n)} \) and \( T_{2, i, j}^{(n)} \).
3) Set \( j := 1 \).
4) Compute \( \nabla G_j R_{\text{wsum, finite}}(G_1^{(n)}, G_2^{(n)}, \cdots, G_K^{(n)}) = \frac{\log_2 e}{\sigma^2} \left( \sum_{i=1}^{K} \mu_i H_{ii}^H T_{1, i, j}^{(n)} - \sum_{i=1, i \neq j}^{K} \mu_i H_{ij}^H T_{2, i, j}^{(n)} \right) \).
5) Set step size \( t := 1 \).
6) Evaluate:

\[
c = \alpha t \parallel \nabla G_j R_{\text{wsum, finite}}(G_1^{(n)}, G_2^{(n)}, \cdots, G_K^{(n)}) \parallel F. \]

If \( c \) is sufficiently small, then go to step 11.
7) Compute:

\[
G_j^{(n+1)} = G_j^{(n)} + c \nabla G_j R_{\text{wsum, finite}}(G_1^{(n)}, G_2^{(n)}, \cdots, G_K^{(n)}).
\]

8) If \( \left( G_j^{(n+1)}^H G_j^{(n+1)} \right) > P_j \), update \( G_j^{(n+1)} = \sqrt{\text{tr}(G_j^{(n+1)} G_j^{(n+1)})} \); Otherwise, \( G_j^{(n+1)} = G_j^{(n)} \).
9) Compute:

\[
R_{\text{wsum, finite}}(G_1^{(n+1)}, G_2^{(n+1)}, \cdots, G_K^{(n+1)}), T_{1, i, j}^{(n+1)} \text{ and } T_{2, i, j}^{(n+1)}.
\]

10) If \( R_{\text{wsum, finite}}(G_1^{(n+1)}, G_2^{(n+1)}, \cdots, G_K^{(n+1)}) > P_j \), set \( t := \beta t \).

It is noted that step 7 in Algorithm 1 updates the new precoder \( G_j^{(n+1)} \) along its gradient descent direction. This is an efficient approach in searching the optimal precoder \( G_j \). However, this might result in a new precoder \( G_j^{(n+1)} \) which does not satisfy the power constraint. In this case, according to the conclusion in [34], the best solution is to project \( G_j^{(n+1)} \) to the boundary of the feasible set. At the start of the iteration, the initial weighted sum-rate is low. Thus, the weighted sum-rate will be increased with the new precoder \( G_j^{(n+1)} \) that satisfies the individual power constraint. This has been confirmed in various scenarios in [21, 23, 25, 34]. After several iteration steps, the weighted sum-rate might be high and it might not be able to find a feasible new precoder \( G_j^{(n+1)} \) that still increases the weighted sum-rate. Hence, in step 6, we set a condition that when \( c \) is sufficiently small, which corresponds to the sufficiently small step \( t \), the update process stops and Algorithm 1 goes to step 11 directly.
and computations of matrices multiple times, and choose the resulting precoders of the objective function. Thus, it is guaranteed to converge. Due to the non-concavity of the objective function $R_{\text{wsum, finite}}(G_1, G_2, \ldots, G_K)$, the proposed algorithm may only find local maxima. To mitigate the local convergence, we randomly initialize the precoding matrices multiple times, and choose the resulting precoders with the maximum WSR performance to be the final solution [18, 21, 23].

The complexity of Algorithm 1 mainly depends on the computations of $R_{\text{wsum, finite}}(G_1, G_2, \ldots, G_K)$, $T_{1,i,j}$ and $T_{2,i,j}$, $i = 1, 2, \ldots, K, j = 1, 2, \ldots, K$. From (7), (19), (25) and (26), we note that the computations of $R_{\text{wsum, finite}}(G_1, G_2, \ldots, G_K)$, $T_{1,i,j}$ and $T_{2,i,j}$ involve summations of all the elements in the modulation set from all users. Hence, the complexity of Algorithm 1 grows exponentially with $N_{\text{Total}}$, where $N_{\text{Total}} = \frac{1}{\log_2 e} \sum_{j=1}^{K} N_j \log_2 Q_j$.

D. Iterative Receiver for MIMO Interference Channels

In Algorithm 1, we have considered the linear precoding design with finite alphabet inputs from the information theoretical perspective. However, another major concern in practical communication systems is the coded BER performance. To further examine the benefits of the proposed design, here we present transceiver structures in MIMO interference channels to evaluate the coded BER performance of the obtained precoders, which are illustrated in Figures 2 and 3.

In Figure 2, LDPC channel code is assumed for all the transmitters, prior to the linear precoder designed by Algorithm 1. In Figure 3, the turbo principle [35] is adopted at each receiver side where the detector and the LDPC channel decoder iteratively exchange their soft information. $\Pi$ and $\Pi^{-1}$ in Figure 2 and Figure 3 denote the interleaver and de-interleaver respectively. At the final iteration, hard decisions are made at each user side to obtain the estimations of the transmitted bits and the overall performance is evaluated by averaging the error rate among all the $K$ users.

Here, we choose the MAP detection method for the “MIMO IC Soft Detector” in Figure 3, due to its near-capacity performance$^5$ [36]. If the Gaussian input assumption is adopted, the interference for each user in (1) can be modeled as colored noise.
the channel matrices for two users are fixed (non-fading),

\[ C_j = \sum_{i=1}^{K} H_{ij} G_i G_i^H H_{ji} + \sigma^2 I_{N_i}, \quad j = 1, 2, \cdots, K. \]  

(27)

We can whiten the interference-plus-noise vectors by multiplying \( C_j^{-1/2} \) to obtain

\[ \bar{y}_j = C_j^{-1/2} y_j, \quad j = 1, 2, \cdots, K. \]  

(28)

Then, the MAP detection method for point-to-point MIMO scenarios can be applied to evaluate the coded BER performance of each user.

However, for practical finite alphabet signals, the interference in (1) is not Gaussian distributed. Here we provide a MAP detection structure which does not require the Gaussian interference assumption. For the \( j \)-th user with received vector \( y_j \), the extrinsic LLR \( L_E(s_{j,i}) \) can be expressed as [36]

\[ L_E(s_{j,i}) = \log_2 \frac{\sum_{s_{j,i} \in S_{j,i,+}} p(y_j | x_j = \text{map}(s_{j,i})) \exp \left( \frac{1}{\sigma^2} s_{j,i} L_A(s_{j,i}) \right)}{\sum_{s_{j,i} \in S_{j,i,-}} p(y_j | x_j = \text{map}(s_{j,i})) \exp \left( \frac{1}{\sigma^2} s_{j,i} L_A(s_{j,i}) \right)}. \]  

(29)

where \( s_{j,i} \) denotes the \( i \)-th bit of the \( j \)-th user, with \( 1 \leq i \leq N_j M_j \), and \( 1 \leq j \leq K \). The \( N_j M_j \times 1 \) vector \( s_j \) represents the coded bits for the \( j \)-th user. \( S_{j,i,+} \) and \( S_{j,i,-} \) are the sets of \( 2^{N_j M_j-1} \) bit vectors with the \( i \)-th element being \( +1 \) and \( -1 \), respectively. \( s_{j,i} \) demonstrates the subvector of \( s_j \) by omitting the \( i \)-th elements. \( L_A(s_{j,i}) \) is the \((N_j M_j - 1) \times 1 \) vector with the \textit{a priori} information of \( s_{j,i} \). \( x_j = \text{map}(s_j) \) denotes the modulation from the bit vector \( s_j \) to symbol vector \( x_j \). For the MIMO interference channel systems (1), we have the likelihood function

\[ p(y_j | x_j = \text{map}(s_j)) = \frac{1}{(2\pi \sigma^2)^{N_j M_j}} \prod_{m_1=1}^{M_1} \cdots \prod_{m_{K-1}=1}^{M_{K-1}} \sum_{m_K=1}^{M_K} \cdot \sum_{m_{j+1}=1}^{M_{j+1}} \exp \left( -\frac{1}{2\sigma^2} \sum_{t=1}^{K} H_{jt} G_j x_j - \frac{K}{\sigma^2} \right). \]  

(30)

\[ \]  

**IV. Numerical Results**

In this section, we provide numerical results to examine the performance of the proposed iterative optimization algorithm. We assume equal individual power limit \( P_1 = \cdots = P_K = P \), normalized channel matrices, and the same modulation for all \( K \) users. Then, the average SNR of the MIMO interference channel systems is given by [15] \( \text{SNR} = P/\sigma^2 \). It is noted that all the channel matrices in this section are generated randomly.

First, we consider a 2-user MIMO interference channel system with two transmit and two receive antennas for each user. Similar to [21], for illustrative purpose, here we assume the channel matrices for two users are fixed (non-fading), which are given by

\[ H_{11} = \begin{pmatrix} 1.2813 & 0.1578 + 0.3445j \\ 0.1578 - 0.3445j & 0.2666 \end{pmatrix}, \]  

\[ H_{12} = \begin{pmatrix} 0.4596 & 0.0332 - 0.5936j \\ 0.0332 + 0.5936j & 1.0401 \end{pmatrix}, \]  

\[ H_{21} = \begin{pmatrix} 0.3523 & -0.3938 + 0.3207j \\ -0.3938 - 0.3207j & 1.1662 \end{pmatrix}, \]  

\[ H_{22} = \begin{pmatrix} 0.2483 & 0.3246 + 0.2157j \\ 0.3246 - 0.2157j & 1.2785 \end{pmatrix}. \]

Figures 4 and 5 show the convergence behaviors of the proposed algorithm at different SNRs and under different modulations for the sum-rate \((\mu_1 = \mu_2 = 1)\) maximization. For backtracking line search in Algorithm 1, the typical parameters are chosen as \( \alpha = 0.1 \) and \( \beta = 0.5 \) [33]. Statistical averages in (7) and (21) are evaluated via Monte Carlo drawings of 1000 random samples. These figures illustrate the evolutions of the sum-rate for each iterative step. We can see that in all the cases, the proposed algorithm converges within about 10 iteration steps.

![Fig. 4: Convergence of sum rate maximization with BPSK modulation.](image)

Figure 6 compares the sum-rate performances\(^6\) of BPSK modulation under different transmit precoding schemes. We extend the idea for two-user SISO interference channels in [26] by a numerical search for the best rotation angle \( \theta \) for the second user constellation set \( e^{j\theta} x_{2,j}, j = 1, 2, \cdots, M_2, \theta \in [0, 2\pi) \), which is denoted as “BPSK, Best Rotation”. With respect to “BPSK, Gaussian Design”, we implement the Gaussian input assumption linear precoding design by the iterative algorithm in [15], and compute the finite alphabet rate of this

\(\)\(^6\) It is noted that practical techniques can be employed in the random initial point selection process. For instance, the initial precoder at current SNR level can be generated by a weighted combination of the final precoder obtained at previous SNR level and a randomly generated precoder. Since the SNR step in our simulation is not large, this can take advantage of the previously computed precoder and accelerate the convergence speed. In general, for finite alphabet input signals, the WSR value lies in a limited bounded space. Therefore, 2-3 times random initializations are often sufficient to achieve a near-optimal WSR performance.
The performances of the “Low SNR Design” and the “High SNR Design” are about 4.5 dB and 10 dB, respectively. Note that the sum-rate performances of the “High SNR Design” achieve \( \sum_{j=1}^{K} \log_2 M_j = 8 \) b/s/Hz in high SNR region. Furthermore, we observe that in both BPSK and QPSK cases, linear precoding design based on Gaussian input assumption performs almost identically as the proposed precoding in low SNR region, which corroborates the conclusion in Corollary 1.

For BPSK modulation, the final precoding matrices obtained via Algorithm 1 when SNR = 5 dB are given by

\[
G_1 = \begin{bmatrix}
0.5390 - 0.7978j & 1.0204 + 0.1993j \\
-1.0166 - 0.1732j & 0.2907 + 0.0809j \\
\end{bmatrix}
\]

\[
G_2 = \begin{bmatrix}
-0.0063 + 0.0404j & 0.2802 - 0.3445j \\
1.2232 + 0.0059j & 0.6386 - 1.0292j \\
\end{bmatrix}
\]

The sum-rate performances under different transmit precoding schemes with QPSK inputs are illustrated in Figure 7. We have similar observations with the BPSK case, where the proposed precoding achieves higher sum-rate than other precoding schemes, and the sum-rate performance of the “Low SNR Design” matches closely with the performance of the Gaussian input case in low SNR region.

As a more comprehensive comparison, we obtain the coded BER performances of a 2-user MIMO interference channel system illustrated in Figure 2 and 3. The LDPC encoder and

1It should be noted that as the constellation size increases, the performance gap between the finite alphabet input design and the Gaussian input design will decrease.
decoder simulation package [38] is used, for coding rate $3/4$ and coding length $L = 9600$. The MAP detector given in (29) is employed. The number of iterations between the MAP detector and the LDPC decoder is set to 5. Figure 8 plots the coded BER curves with different precoding schemes under BPSK modulation. We observe from Figure 8 that, at a targeted BER of $10^{-4}$, the corresponding SNR gains of the proposed precoding over “BPSK, Best Rotation” and “BPSK, Gaussian Design” schemes are about 7 dB and 13.5 dB, respectively. This suggests that the proposed precoding is very promising as it shows direct improvement on the coded BER performance in practical systems. Furthermore, comparing the performances of the proposed precoding and the Gaussian schemes in Figure 6 and Figure 8, we note that the SNR gains for the coded BER are larger than the corresponding SNR gains for the sum-rate shown in Figure 6. The reason for this observation is that we average the coded BER of 2 users to generate Figure 8. Therefore, the average coded BER is dominated by the user with larger coded BER.

![Fig. 8: BER of 2-user MIMO interference channels with BPSK modulation.](image1)

![Fig. 9: Mutual information for individual user with BPSK modulation.](image2)

![Fig. 10: BER of 2-user MIMO interference channels with QPSK modulation.](image3)

To confirm this, we present the mutual information of individual users under different precoding schemes and BPSK modulation in Figure 9. It is revealed in Figure 9 that, e.g., although the sum-rate is above 3 b/s/Hz for the Gaussian precoder design when SNR = 14 dB, the achievable rate for user 1 is below 1.5 b/s/Hz. Therefore, the overall coded BER is still high for the Gaussian design in Figure 8 when SNR = 14 dB. Also, we can observe from Figure 9 that the SNR gain for the user 1 of the proposed precoding over user 1 of the Gaussian design at rate 1.5 b/s/Hz is about 13.5 dB. The results correspond to the SNR gains for the coded BER in Figure 8.

Figure 10 depicts the coded BER curves with QPSK inputs. The observations in Figure 10 are similar with the BPSK case. At a targeted coded BER of $10^{-4}$, the proposed precoding design has 5.5 dB and 10 dB SNR gains over “QPSK, Best Rotation” and “QPSK, Gaussian Design”, respectively. Also, the coded BER results coincide with the mutual information results for individual users under QPSK modulation and different precoder designs as shown in Figure 11.

![Fig. 11: Mutual information for individual user with QPSK modulation.](image4)

Next, the coded BER performances of using the detection method in (28) (denoted as “Gaussian Assumption Detection”) and the detection method in (29) (denoted as “Proposed Detection”) under different modulations are compared. Simulation results are listed in Table I. The precoders obtained via Algorithm 1 are used at the transmitter. From the results shown in Table I, it is seen that the “Proposed Detection” achieves lower BER than the “Gaussian Assumption Detection”, which indicates that exploiting the interference constellation structure can lead to additional performance gains in practical systems.

Finally, we further investigate the precoding design in a 3-user MIMO interference channel system. The channel matrices
are given by

\[
\begin{align*}
H_{11} &= \begin{pmatrix}
-0.2279 - 0.6039j & 0.0660 + 0.6264j \\
-0.8774 + 0.6273j & 0.1515 - 0.0198j
\end{pmatrix}, \\
H_{12} &= \begin{pmatrix}
0.1915 - 0.3442j & -0.1092 - 0.0798j \\
0.1022 + 1.2773j & 0.4246 + 0.0667j
\end{pmatrix}, \\
H_{13} &= \begin{pmatrix}
0.5759 + 0.1583j & -0.1092 - 0.0798j \\
0.1022 + 1.2773j & 0.4246 + 0.0667j
\end{pmatrix}, \\
H_{21} &= \begin{pmatrix}
-0.3382 - 0.7046j & 0.6131 - 0.1955j \\
0.4195 + 0.2793j & -0.7792 + 0.3374j
\end{pmatrix}, \\
H_{22} &= \begin{pmatrix}
0.4643 + 0.6778j & 0.7344 - 0.0113j \\
0.4052 - 0.6845j & 0.3806 - 0.0892j
\end{pmatrix}, \\
H_{23} &= \begin{pmatrix}
-0.8238 - 0.4134j & 0.5425 + 0.1126j \\
0.1321 + 0.2715j & 0.7267 - 0.4734j
\end{pmatrix}, \\
H_{31} &= \begin{pmatrix}
-0.9707 + 0.2271j & -0.4520 - 0.2644j \\
-0.0265 - 0.7569j & 0.2748 - 0.2878j
\end{pmatrix}, \\
H_{32} &= \begin{pmatrix}
-0.2200 - 0.0000j & -0.0113 + 0.6334j \\
-0.5837 - 0.1839j & -0.0279 - 1.0840j
\end{pmatrix}, \\
H_{33} &= \begin{pmatrix}
-0.2200 - 0.0000j & -0.0113 + 0.6334j \\
-0.5837 - 0.1839j & -0.0279 - 1.0840j
\end{pmatrix}.
\]

Figure 12 compares the sum-rate performances of different precoding designs with BPSK inputs. The sum-rates achieved by the proposed “Finite Alphabet Input High SNR Design” and the “Interference Alignment Technique” are also plotted. It is observed from Figure 12 that the proposed precoding outperforms other precoding designs. At a targeted sum-rate of 4.5 b/s/Hz, our proposed precoding has about 10 dB SNR gains over the Gaussian design. Moreover, the sum-rate performances with QPSK inputs are plotted in Figure 13. At a targeted sum-rate of 9 b/s/Hz, the performance gains of the proposed precoding over the Gaussian design are about 8 dB. We note that, in both modulations, the sum-rates achieved by the “Finite Alphabet Input High SNR Design” saturate at $R_{\text{sum}}^{\text{QPSK}} = \sum_{j=1}^{K} \log_2 M_j$ b/s/Hz, and the “Interference...
Alignment” has 50% sum-rate losses\(^8\) as implied in Corollary 2.

V. CONCLUSION

This work investigated the linear precoding design for MIMO interference channel systems. To break away from the traditional studies based on Gaussian input assumption, we formulated the problem of maximizing mutual information for finite alphabet inputs. We derived the achievable rate expression of each user. Our analysis at the high SNR revealed that the IA technique designed for Gaussian input case will lead to a significant sum-rate loss due to the utilization of partial interference-free signal space for transmission. In light of this, we developed an efficient power allocation scheme designed for finite alphabet input scenario at high SNR. The proposed scheme achieves the analytical upper-bound sum-rate of the entire signal space \(\sum_{j=1}^{K} \log_2 M_j\) b/s/Hz under finite alphabet constraints. More generally, we derived a set of necessary conditions for the WSR maximization precoding design based on Karush-Kuhn-Tucker (KKT) analysis, from which we developed an iterative algorithm for precoding optimization. We applied gradient descent optimization and used backtracking line search algorithm to regulate the convergence speed. Our tests, based on LDPC coded QAM signals in the MIMO interference channels established the coded BER performance gain of the obtained linear precoders.

ACKNOWLEDGMENT

The authors would like to thank the editor, Prof. Tony Q. S. Quek, and anonymous reviewers for helpful comments and suggestions that greatly improved the quality of the paper.

APPENDIX A

PROOF OF PROPOSITION 1

When the discrete input data vector \(x_k\) is independent and uniformly distributed from the constellation set \(S_j\), the a priori probabilities of \(x_{j,p}\) is \(p(x_{j,p}) = \frac{1}{M_j}\), \(p = 1, 2, \ldots, M_j\), \(j = 1, 2, \ldots, K\). Then, according to the definition of conditional entropy [39] and the Bayes’ theorem, we can evaluate \(H(y_j)\) and \(H(y_j | x_j)\) given in (31) and (32) at the top of the next page.

From model (1), we have

\[
p(y_j | x_{1,m_1}, x_{2,m_2}, \ldots, x_{K,m_K}) = \frac{1}{(\pi\sigma^2)^{\gamma_j}} \exp\left(-\frac{\|y_j - \sum_{i=1}^{K} H_{ij} G_i x_{i,m_i}\|^2}{\sigma^2}\right)
\]

\[
(33)
\]

\[
p(y_j | x_{j,m_j}, x_{1,n_1}, \ldots, x_{j-1,n_j-1}, x_{j+1,n_{j+1}}, \ldots, x_{K,n_K}) = \frac{1}{(\pi\sigma^2)^{\gamma_j}} \exp\left(-\frac{\|y_j - H_{ij} G_i x_{j,m_j} - \sum_{i=1,i\neq j}^{K} H_{ij} G_i x_{i,n_i}\|^2}{\sigma^2}\right)
\]

\[
(35)
\]

Plugging (33)–(35) into (31) and (32) and define \(n = y_j - \sum_{i=1}^{K} H_{ij} G_i x_{i,m_i}\), yields

\[
H(y_j) = \sum_{i=1}^{K} \log_2 M_i - \frac{1}{\prod_{i=1}^{K} M_i} \sum_{m_1=1}^{M_1} \sum_{m_2=1}^{M_2} \cdots \sum_{m_K=1}^{M_K} \int p(n) \log_2 H_{1,j} (m_1, m_2, \ldots, m_K, n) \, dn
\]

\[
= \sum_{i=1}^{K} \log_2 M_i - \frac{1}{\prod_{i=1}^{K} M_i} \sum_{m_1=1}^{M_1} \sum_{m_2=1}^{M_2} \cdots \sum_{m_K=1}^{M_K} E_n [\log_2 H_{1,j} (m_1, m_2, \ldots, m_K, n)]
\]

\[
(36)
\]

\[
H(y_j | x_j) = \sum_{i=1, i \neq j}^{K} \log_2 M_i - \frac{1}{\prod_{i=1}^{K} M_i} \sum_{m_1=1}^{M_1} \sum_{m_2=1}^{M_2} \cdots \sum_{m_K=1}^{M_K} \sum_{j=1}^{M_j} \int p(n) \log_2 H_{2,j} (m_1, \ldots, m_{j-1}, m_{j+1}, \ldots, m_K, n) \, dn
\]

\[
= \sum_{i=1, i \neq j}^{K} \log_2 M_i - \frac{1}{\prod_{i=1}^{K} M_i} \sum_{m_1=1}^{M_1} \sum_{m_2=1}^{M_2} \cdots \sum_{m_K=1}^{M_K} \sum_{j=1, i \neq j}^{M_j} E_n [\log_2 H_{2,j} (m_1, \ldots, m_{j-1}, m_{j+1}, \ldots, m_K, n)].
\]

\[
(37)
\]

Then, the proposition is proved by utilizing the definition of the mutual information [39] \(R_j = I(y_j, x_j) = H(y_j) - H(y_j | x_j)\), along with the expressions in (37) and (39).

APPENDIX B

PROOF OF PROPOSITION 2

First, we apply Jensen’s inequality [33] to obtain an approximation of (7) as follows

\[
R_{j, \text{finite}} \approx \log M_j - \frac{1}{\prod_{i=1}^{K} M_i} \times \left[f_1 \left(E_n \exp \left(-\frac{1}{\sigma^2} \left\| \sum_{i=1}^{K} H_{ij} G_i (x_{i,m_i} - x_{i,n_i}) + n \right\|^2 \right) \right] - f_2 \left(E_n \exp \left(-\frac{1}{\sigma^2} \left\| \sum_{i=1,i\neq j}^{K} H_{ij} G_i (x_{i,m_i} - x_{i,n_i}) + n \right\|^2 \right) \right]\right]
\]

\[
(40)
\]
\[
H (y_j) = \sum_{i=1}^{K} \log_2 M_i + \frac{1}{\prod_{i=1}^{K} M_i} \sum_{m_1=1}^{M_1} \sum_{m_2=1}^{M_2} \cdots \sum_{m_K=1}^{M_K} \int p (y_j | x_{1,m_1}, x_{2,m_2}, \ldots, x_{K,m_K}) 
\times \log_2 \frac{\sum_{n_1=1}^{M_1} \cdots \sum_{n_K=1}^{M_K} p (y_j, x_{1,n_1}, x_{2,n_2}, \ldots, x_{K,n_K})}{\sum_{n_1=1}^{M_1} \cdots \sum_{n_K=1}^{M_K} p (y_j, x_{1,n_1}, x_{2,n_2}, \ldots, x_{K,n_K})} dy_j 
\]

(31)

\[
H (y_j | x_j) = \sum_{i=1, i \neq j}^{K} M_i + \frac{1}{\prod_{i=1}^{K} M_i} \sum_{m_1=1}^{M_1} \sum_{m_2=1}^{M_2} \cdots \sum_{m_K=1}^{M_K} \int p (y_j | x_{1,m_1}, x_{2,m_2}, \ldots, x_{K,m_K}) 
\times \log_2 \frac{\sum_{n_1=1}^{M_1} \cdots \sum_{n_K=1}^{M_K} p (y_j, x_{1,n_1}, x_{2,n_2}, \ldots, x_{K,n_K})}{\sum_{n_1=1}^{M_1} \cdots \sum_{n_K=1}^{M_K} p (y_j, x_{1,n_1}, x_{2,n_2}, \ldots, x_{K,n_K})} dy_j.
\]

(32)

where we define the operations \(f_1(\cdot), f_2(\cdot), f_3(\cdot)\) and \(f_4(\cdot)\) as

\[
f_1(\cdot) = \sum_{m_1=1}^{M_1} \sum_{m_2=1}^{M_2} \cdots \sum_{m_K=1}^{M_K} \log_2 M_i \sum_{n_1=1}^{M_1} \cdots \sum_{n_K=1}^{M_K} \cdot (\cdot)
\]

(41)

\[
f_2(\cdot) = \sum_{m_1=1}^{M_1} \sum_{m_2=1}^{M_2} \cdots \sum_{m_K=1}^{M_K} \log_2 M_i \sum_{n_1=1}^{M_1} \cdots \sum_{n_K=1}^{M_K} \cdot (\cdot)
\]

(42)

\[
f_3(\cdot) = \sum_{m_1=1}^{M_1} \sum_{m_2=1}^{M_2} \cdots \sum_{m_K=1}^{M_K} \sum_{n_1=1}^{M_1} \cdots \sum_{n_K=1}^{M_K} \cdot (\cdot)
\]

(43)

\[
f_4(\cdot) = \sum_{m_1=1}^{M_1} \sum_{m_2=1}^{M_2} \cdots \sum_{m_K=1}^{M_K} \sum_{n_1=1}^{M_1} \cdots \sum_{n_K=1}^{M_K} \cdot (\cdot).
\]

(44)

Recalling the definition of \(n\) in (7), the first expectation in (40) can be evaluated as

\[
E_n \exp \left( -\frac{1}{\sigma^2} \left\| \sum_{i=1}^{K} H_{ji} G_i (x_{i,m_i} - x_{i,n_i}) + n \right\| ^2 \right)
= \int_n \exp \left( -\frac{1}{\sigma^2} \left\| \sum_{i=1}^{K} H_{ji} G_i (x_{i,m_i} - x_{i,n_i}) + n \right\| ^2 \right)
\times \exp \left( -\frac{\|n\|^2}{2\sigma^2} \right) d\mathbf{n} \times (\pi \sigma^2)^{-N_r}
\]

(45)

\[
= 2^{-N_r} \exp \left( -\frac{1}{\sigma^2} \left\| \sum_{i=1}^{K} H_{ji} G_i (x_{i,m_i} - x_{i,n_i}) \right\| ^2 \right)
\times \int_n I_1 (n) \, d\mathbf{n}
\]

(46)

where

\[
I_1 (n) = \left( \frac{\pi \sigma^2}{2} \right)^{-N_r} \times \exp \left( -\frac{2}{\sigma^2} \left\| \sum_{i=1}^{K} \frac{1}{2} H_{ji} G_i (x_{i,m_i} - x_{i,n_i}) + n \right\| ^2 \right)
\]

(47)

denotes a probability density function of an independent and identically distributed Gaussian vector with mean \(-\frac{1}{2} \sum_{i=1}^{K} H_{ji} G_i (x_{i,m_i} - x_{i,n_i})\) and covariance matrix \(\frac{\sigma^2}{2} \mathbf{I}\). Therefore, we have

\[
\int_n I_1 (n) \, d\mathbf{n} = 1.
\]

(48)

Combining (45)-(48) and applying similar approaches to the second expectation in (40), yields \(\tilde{R}_{j,\text{finite}}\) as follows

\[
\tilde{R}_{j,\text{finite}} = \log M_j - \frac{1}{\prod_{i=1}^{K} M_i} \times
\left[
\begin{array}{c}
f_1 \left( \exp \left( -\frac{1}{2\sigma^2} \left\| \sum_{i=1}^{K} H_{ji} G_i (x_{i,m_i} - x_{i,n_i}) \right\| ^2 \right) \right) \right) - \\
\left( f_2 \left( \exp \left( -\frac{1}{2\sigma^2} \left\| \sum_{i=1, i \neq j}^{K} H_{ji} G_i (x_{i,m_i} - x_{i,n_i}) \right\| ^2 \right) \right) \right) 
\end{array}
\right].
\]

(49)

It is noted that here we use the Jensen’s inequality in two terms in (7) and then subtract them. When SNR is zero, the approximated rate \(\tilde{R}_{j,\text{finite}}\) in (49) is zero, which corresponds to the exact achievable rate in (7). This indicates that the approximation based on Jensen’s inequality is asymptotically accurate when SNR goes to zero. In addition, since the “bounding errors” for both terms are to be similar and therefore subtracting these will have a canceling effect, which in turn will yield a fairly accurate approximation. This will be confirmed by numerical results where the obtained precoding design based on (49) performs nearly close to sum-rate achieved by Gaussian inputs in low SNR region, which implies the obtained precoding design is actually near-optimal over all the possible solution sets.

In low SNR region where \(\sigma^2 \rightarrow +\infty\), utilizing the Taylor expansion of the exponent function \(\exp(x) = 1 + x + o(x)\), (49) can be computed as

\[
\tilde{R}_{j,\text{finite}} = \log M_j - \frac{1}{\prod_{i=1}^{K} M_i} \times
\left[
\begin{array}{c}
f_1 \left( 1 - \frac{1}{2\sigma^2} \left\| \sum_{i=1}^{K} H_{ji} G_i (x_{i,m_i} - x_{i,n_i}) \right\| ^2 \right) + o \left( \frac{1}{\sigma^2} \right) \right) - \\
\left( f_2 \left( 1 - \frac{1}{2\sigma^2} \left\| \sum_{i=1, i \neq j}^{K} H_{ji} G_i (x_{i,m_i} - x_{i,n_i}) \right\| ^2 \right) + o \left( \frac{1}{\sigma^2} \right) \right) 
\end{array}
\right].
\]

(50)

Next, we exploit the Taylor expansion of function \(\log_2(1 - \frac{1}{2\sigma^2} \left\| \sum_{i=1}^{K} H_{ji} G_i (x_{i,m_i} - x_{i,n_i}) \right\| ^2 \right) + o \left( \frac{1}{\sigma^2} \right) \).
\[ x = -\log_2 e x + o(x) \text{ to rewrite (51) as} \]

\[
\hat{R}_{j,\text{finite}} = \frac{\log_2 e}{2\sigma^2} \left( \prod_{i=1}^{K} M_i \right) \sum_{i=1}^{K} f_3 \left( \text{tr} \left( H_{ji} G_i (x_{i,m_i} - x_{i,n_i}) \right) \right) \]

\[ \times \left( x_{i,m_i} - x_{i,n_i} \right)^{H} G_i^{H} H_{ji}^{H} - M_j \sum_{i=1,i\neq j}^{K} f_4 \left( \text{tr} \left( H_{ji} G_i \right) \right) \]

\[ \times \left( x_{i,m_i} - x_{i,n_i} \right)^{H} G_i^{H} H_{ji}^{H} \right) + o \left( \frac{1}{\sigma^2} \right). \]  

\[
(51)
\]

For practical equiprobable symbols from symmetrical discrete constellation, we have

\[
\sum_{m=1}^{M_i} x_{j,m} x_{j,m}^{H} = M_i, \quad \sum_{m=1}^{M_i} x_{j,m} x_{j,m}^{H} = 0, \quad j = 1, 2, \cdots, K.
\]

(52)

To this end, (51) can be further reduced to

\[
\hat{R}_{j,\text{finite}} = \frac{\log_2 e}{\sigma^2} \left( \prod_{i=1}^{K} M_i \right) ^{1/2} \sum_{i=1}^{K} \text{tr} \left( H_{ji} G_i G_i^{H} H_{ji}^{H} \right) \]

\[ - \left( \prod_{i=1}^{K} M_i \right) ^{1/2} \sum_{i=1,i\neq j}^{K} \text{tr} \left( H_{ji} G_i G_i^{H} H_{ji}^{H} \right) + o \left( \frac{1}{\sigma^2} \right). \]  

\[
(53)
\]

In (53), the achievable rate of each user is determined by its own channel gain and precoding matrix. Also, it is straightforward to identify that the precoding design maximizing the first-order term in (53) is to perform beamforming along the eigenvector corresponding to the largest eigenvalue of matrix \( H_{jj}^{H} H_{jj} \), which completes the proof.

**APPENDIX C**

**PROOF OF COROLLARY 1**

Here we prove that in low SNR region, the optimal precoding under Gaussian input assumption conforms to the precoding structure in Proposition 2. First, we rewrite achievable rate under Gaussian input assumption in (3) as

\[
R_j(u) = \log_2 \det \left( I + u \sum_{i=1}^{K} H_{ji} G_i G_i^{H} H_{ji}^{H} \right) - \log_2 \det \left( I + u \sum_{i=1,i\neq j}^{K} H_{ji} G_i G_i^{H} H_{ji}^{H} \right) \]

\[
(54)
\]

where \( u = \frac{1}{\sigma^2} \). In low SNR region, we expand \( R_j(u) \) with respect to \( u \) at \( u = 0 \) as

\[
R_j(u) \approx R_j(0) u + o(u). \]  

(55)

By exploiting [40, Lemma 2], we have

\[
\frac{d}{du} \log_2 \det (I + uX) \big|_{u=0} = \log_2 e \text{ tr} \left( X \right). \]  

(56)

Combining (54)–(56), yields

\[
R_j = \frac{\log_2 e}{\sigma^2} \text{tr} \left( H_{jj} G_j G_j^{H} H_{jj}^{H} \right) + o \left( \frac{1}{\sigma^2} \right). \]  

(57)

We note that the precoding structure in Proposition 2 also maximizes the first-order term in (57), which completes our proof. Moreover, the results in (53) and (57) implies that (53) actually provides a first-order term upper bound for the achievable rate of each user with finite alphabet inputs in low SNR region.

**APPENDIX D**

**PROOF OF PROPOSITION 3**

First, we consider \( H_{ji}(m_1, m_2, \cdots, m_K, n) \). When \( \sigma^2 \rightarrow 0 \), we know if \( \sum_{i=1}^{K} H_{ji} G_i (x_{i,m_i} - x_{i,n_i}) \neq 0 \), it yields

\[
\lim_{\sigma^2 \rightarrow 0} \exp \left( \frac{\left( \sum_{i=1}^{K} H_{ji} G_i (x_{i,m_i} - x_{i,n_i}) + n \right)^2}{\sigma^2} \right) = 0.
\]

(58)

We consider the arrays \( (m_1, m_2, \cdots, m_K) \neq (n_1, n_2, \cdots, n_K) \). If \( m_1 \neq n_1 \), we define

\[
c_{j,t}^{1,1} (m_1, n_1) = \sqrt{\frac{P_1}{N_1}} a_{1,j,m_1,n_1,t} \]

\[
c_{j,t}^{1,2} (m_2, m_3, \cdots, m_K, n_2, n_3, \cdots, n_K)
\]

\[
= \frac{K}{i=2} \sqrt{\frac{P_1}{N_1}} a_{1,i,j,m_i,n_i,t}.
\]

(59)

(60)

Since \( m_1 \neq n_1 \), we can always find a \( t^* \in [1, N_{c_j}] \), satisfies

\[
\left| c_{j,t^*}^{1,1} (m_1, n_1) \right| \geq \frac{P_1}{N_1} \omega_{1,\min}
\]

\[
\left| c_{j,t^*}^{1,2} (m_2, m_3, \cdots, m_K, n_2, n_3, \cdots, n_K) \right|
\]

\[
\leq \sum_{i=2}^{K} \sqrt{\frac{P_1}{N_1}} | a_{1,i,j,m_i,n_i,t^*} | \leq \frac{K}{i=2} \sqrt{\frac{P_1}{N_1}} \omega_{1,\max}
\]

(61)

(62)

where (a) is from the Minkowski’s inequality [41]. Then, combining (61), (62), and the conditions in (16) \((i = 1)\), we have

\[
\left| c_{j,t^*}^{1,1} (m_1, n_1) \right| > \left| c_{j,t^*}^{1,2} (m_2, m_3, \cdots, m_K, n_2, n_3, \cdots, n_K) \right|.
\]

(63)

implies that

\[
c_{j,t^*}^{1,1} (m_1, n_1) + c_{j,t^*}^{1,2} (m_2, m_3, \cdots, m_K, n_2, n_3, \cdots, n_K) \neq 0
\]

(64)

for arbitrary arrays \( (m_1, m_2, \cdots, m_K) \neq (n_1, n_2, \cdots, n_K) \).

If \( m_1 = n_1 \) and \( m_2 \neq n_2 \), we define

\[
c_{j,t}^{2,1} (m_2, n_2) = \sqrt{\frac{P_2}{N_2}} a_{2,j,m_2,n_2,t}
\]

\[
c_{j,t}^{2,2} (m_3, m_4, \cdots, m_K, n_3, n_4, \cdots, n_K)
\]

\[
= \sum_{i=3}^{K} \sqrt{\frac{P_2}{N_2}} a_{1,i,j,m_i,n_i,t}.
\]

(65)

(66)

Following the similar approaches above, it obtains

\[
\left| c_{j,t^*}^{2,1} (m_2, n_2) \right| > \left| c_{j,t^*}^{2,2} (m_3, m_4, \cdots, m_K, n_3, n_4, \cdots, n_K) \right|
\]

(67)
\[ c_{j,t}^2 (m_2, n_2) + c_{j,t}^2 (m_3, m_4, \ldots, m_K, n_3, n_4, \ldots, n_K) \neq 0. \] (68)

This process continues until \( m_1 = n_1, m_2 = n_2, \ldots, m_{K-1} = n_{K-1}, m_K \neq n_K \). We define
\[ c_{j,t}^{K,1} (m_0, n_0) = \sqrt{\frac{\varepsilon_k P}{N_t}} a_{K, m, n_0, t}. \] (69)

Obviously we will find a \( t^* \in [1, N_r K] \) satisfying \( c_{j,t}^{K,1} \neq 0 \) due to the fact \( m_K \neq n_K \).

Thus, according to the precoding design in (15), we know that \( \sum_{i=1}^{K} H_{ji} G_{i} (x_{i,m_i} - x_{i,n_i}) \neq 0 \) as long as \((m_1, m_2, \ldots, m_K) \neq (n_1, n_2, \ldots, n_K) \). This suggests
\[ \lim_{\sigma^2 \to 0} H_{1,j}(m_1, m_2, \ldots, m_K, n) = \exp \left( -\frac{\|n\|^2}{\sigma^2} \right). \] (70)

Next, we consider \( H_{2,j}(m_1, m_2, \ldots, m_K) \). Based on the precoding design in (15), if the equality \( \sum_{i=1, i \neq j}^{K} H_{ji} G_{i} (x_{i,m_i} - x_{i,n_i}) = 0 \) holds for any arrays \((m_1, m_2, \ldots, m_{j-1}, m_{j+1}, \ldots, m_K) \neq (n_1, n_2, \ldots, n_{j-1}, n_{j+1}, \ldots, n_K) \), then by setting \( m_j = n_j \), it yields \( \sum_{i=1}^{K} H_{ji} G_{i} (x_{i,m_i} - x_{i,n_i}) = 0 \), which contradicts with the conclusion above. As a consequence, we know that \( \sum_{i=1, i \neq j}^{K} H_{ji} G_{i} (x_{i,m_i} - x_{i,n_i}) \neq 0 \) as long as \((m_1, m_2, \ldots, m_{j-1}, m_{j+1}, \ldots, m_K) \neq (n_1, n_2, \ldots, n_{j-1}, n_{j+1}, \ldots, n_K) \). This implies
\[ \lim_{\sigma^2 \to 0} H_{2,j}(m_1, m_2, \ldots, m_{j-1}, m_{j+1}, \ldots, m_K, n) = \exp \left( -\frac{\|n\|^2}{\sigma^2} \right). \] (71)

Combining (7), (70), and (71), the achievable rate for the \( j \)-th user is given by
\[ \lim_{\sigma^2 \to 0} R_{j, finite} = \log M_j, \quad j = 1, 2, \ldots, K. \] (72)

(72) is the maximum rate that can be achieved for the \( j \)-th user with respect to finite alphabet constraints, which completes the proof.

It is noted that the optimal precoding design when \( \sigma^2 \rightarrow 0 \) is not unique. For any precoders which fulfill the condition \( \sum_{i=1}^{K} H_{ji} G_{i} (x_{i,m_i} - x_{i,n_i}) \neq 0 \) for arrays \((m_1, m_2, \ldots, m_K) \neq (n_1, n_2, \ldots, n_K) \) can achieve the rate in (72).

**APPENDIX E**

**PROOF OF COROLLARY 2**

Based on [13, Theorem 3], we can transform the \( K \) user MIMO interference channel in (1) into a \( KN_T \) user SIMO interference channel with \( \eta \) antenna at each receiver. Let \( \rho = KN_T \eta (K N_T - \eta - 1) \). Then, recalling the interference alignment scheme in [13, Appendix A], the length of desired signal extension for the \( j \)-th user, \( j = 1, 2, \ldots, K \), is given by
\[ l_j = \begin{cases} 
\eta (n+1)^\rho, & j = 1, 2, \ldots, \eta + 1 \\
\eta n^\rho, & j = \eta + 2, \eta + 3, \ldots, KN_T 
\end{cases} \] (73)

At the receiver, each user can decode its desired signal by zero forcing the aligned interference signals. Thus, the sum-rate of all the receivers at high SNR is given by
\[ \tilde{R}_{sum, IA}^\infty (n) = \eta (n+1)^\rho \sum_{j=1}^{\eta+1} \log_2 q_j + \eta n^\rho \sum_{j=\eta+2}^{KN_T} \log_2 q_j \] (74)
where the elements of \( q_j, j = 1, 2, \ldots, KN_T \) are given by
\[ q_j = Q_i, \quad (i-1) N_T + 1 \leq j \leq i N_T, \quad i = 1, 2, \ldots, K. \] (75)
Then, the maximum average sum-rate per symbol can be computed as
\[ \tilde{R}_{sum, IA}^\infty = \sup_n \frac{1}{\nu_n} \tilde{R}_{sum, IA}^\infty (n). \] (76)

By plugging in the expressions of \( \nu_n \) and \( \tilde{R}_{sum, IA}^\infty (n) \) and taking the supremum over all \( n \), it yields
\[ \tilde{R}_{sum, IA}^\infty = \eta \sum_{j=1}^{KN_T} \log_2 q_j = \eta \sum_{j=1}^{K} \log_2 M_j. \] (77)

**APPENDIX F**

**PROOF OF PROPOSITION 4**

The Lagrangian cost function for the precoding matrices in (19)–(20) is given by
\[ f (G, \kappa) = -R_{wsu, finite} (G_1, G_2, \ldots, G_K) + \sum_{j=1}^{K} \kappa_j \left[ \operatorname{tr} (G_j G_j^H) - P_j \right] \] (78)
in which \( \kappa_j \geq 0, j = 1, 2, \ldots, K \). Following the similar approaches in [17], we define the complex gradient operator as \( \nabla G_j^f = \frac{\partial f}{\partial G_j} \). The \((i,j)^{th}\) element of matrix with the gradient is defined as \( \{ \nabla G_j^f \}_{i,j} = \nabla (G_j)_{i,j} f = \frac{\partial f}{\partial G_j}_{i,j} \).

Then, the KKT conditions in [33] are as follows
\[ \nabla G_j^f (G, \kappa) = -\nabla G_{wsu, finite} (G_1, G_2, \ldots, G_K) + \kappa_j G_j = 0 \] (79)
\[ \kappa_j \left[ \operatorname{tr} (G_j G_j^H) - P_j \right] = 0 \] (80)
\[ \operatorname{tr} (G_j G_j^H) - P_j \leq 0 \] (81)
\[ \kappa_j \geq 0 \] (82)

for all \( j = 1, 2, \ldots, K \), where (79) is obtained through the complex matrix differentiation results in [28].

Next, we consider the calculation of \( \nabla G_j R_{wsu, finite} (G_1, G_2, \ldots, G_K) \). For \( R_j (G_1, G_2, \ldots, G_K) \) in (19), we know that \( H_{2,j} (m_1, \ldots, m_{j-1}, m_{j+1}, \ldots, m_K, n_i) \) is independent of \( G_i \) from (9). For \( R_i (G_1, G_2, \ldots, G_K), i \neq j \) in (19), both \( H_{1,i} (m_1, m_2, \ldots, m_K, n_i) \) and \( H_{2,i} (m_1, \ldots, m_{j-1}, m_{j+1}, \ldots, m_K, n_i) \) are functions of \( G_j \). Then, by exploiting the matrix derivative technology in [27], along with some simplifications, we can obtain the derivative expressions \( \nabla G_j R_{wsu, finite} (G_1, G_2, \ldots, G_K) \), given by the right-hand-side of (21).
