THE POSSIBLE EXTREMAL BETTI NUMBERS
OF A HOMOGENEOUS IDEAL

JÜRGEN HERZOG, LEILA SHARIFAN, AND MATTEO VARBARO

(Communicated by Irena Peeva)

Abstract. We give a numerical characterization of the possible extremal Betti numbers (values as well as positions) of any homogeneous ideal in a polynomial ring over a field of characteristic 0.

INTRODUCTION

The main purpose of this note is to characterize the possible extremal Betti numbers (values as well as positions) of any homogeneous ideal in a polynomial ring over a field of characteristic 0. These special graded Betti numbers were introduced by Bayer, Charalambous and Popescu in [BCP]: One reason why they naturally arise is that they are equal to the dimensions of certain cohomology vector spaces of the projective scheme associated to the ideal. We also investigate the possible Betti tables of a componentwise linear ideal. Such a problem seems to be very hard; indeed we could solve it only in some special cases. We provide some examples illustrating the main obstructions to the issue.

After a preliminary section, in Section 2 we study the possible Betti tables of componentwise linear ideals, introduced by Herzog and Hibi in [HH1]. This issue is equivalent to a characterization of the graded Betti numbers of strongly stable ideals. We denote by $I_j$ the $j$th graded component of a strongly stable ideal $I$, set $\mu_{ij}(I)$ equal to the number of the monomials in $I_j \cap K[x_1, \ldots, x_i]$ divisible by $x_i$, and define the matrix $\mathcal{M}(I) = (\mu_{ij}(I))$, which we call the matrix of generators of $I$. As explained at the beginning of Section 2, the matrix $\mathcal{M}(I)$ and the graded Betti numbers of $I$ determine each other. Thus we are led to characterize the integer matrices $(\mu_{ij})$ for which there exists a strongly stable ideal $I$ such that $\mathcal{M}(I) = (\mu_{ij})$. From a result obtained by Murai in [Mu], which yields the characterization of the possible Betti numbers of ideals with linear resolution (see Proposition 2.3), one can deduce some necessary conditions for $(\mu_{ij})$ to be the matrix of generators for some strongly stable ideal; see Proposition 2.6. Unfortunately these conditions are not sufficient to describe the matrices of generators of strongly stable ideals, as shown in Example 2.7. The difficulty of the task of characterizing Betti tables of componentwise linear ideals is also shown by Example 2.8, where we exhibit a noncomponentwise linear ideal (in three variables) with the same Betti table of a componentwise linear ideal, answering negatively a question raised by Nagel.

Key words and phrases. Betti tables, componentwise linear ideals, extremal Betti numbers, strongly stable monomial ideals.
and Römer in [NR]. After discussing the main obstruction to constructing strongly stable ideals with a prescribed matrix of generators, we give sufficient conditions for a matrix to be of the form \( M(I) \), where \( I \) is strongly stable in Proposition 2.9. As a consequence it is shown in Corollary 2.10 that the necessary conditions given in Proposition 2.6 are also sufficient when dealing with strongly stable ideals in three variables. Another instance for which the matrix of generators of a particular class of strongly stable ideals can be described is given in Proposition 2.13, which gives the possible matrices of generators of lexsegment ideals, and therefore, exploiting a result in [HH1] of Gotzmann ideals. Though a complete characterization of the possible matrices of generators of lexsegment ideals, and therefore, exploiting a result in [HH1] of Gotzmann ideals. Though a complete characterization of the possible matrices of generators of lexsegment ideals, and therefore, exploiting a result in [HH1] of Gotzmann ideals.

1. Preliminaries

Let \( n \) be a positive integer. We will essentially work with the polynomial ring

\[ S = K[x_1, \ldots, x_n], \]

where the \( x_i \)'s are variables over a field \( K \). Given a monomial \( u \in S \), we set

\[ m(u) = \max\{e \in \{1, \ldots, n\} : x_e \text{ divides } u\}. \]

A monomial space \( V \subset S \) is called stable if for any monomial \( u \in V \), then \( (u/x_{m(u)}) \cdot x_i \in V \) for all \( i < m(u) \). It is called strongly stable if for any monomial \( u \in V \) and for each \( j \in \{1, \ldots, n\} \) such that \( x_j \) divides \( u \), then \( (u/x_j) \cdot x_i \in V \) for all \( i < j \). Obviously a strongly stable monomial space is stable. By a stable (strongly stable) monomial ideal \( I \subset S \) we mean that the underlying monomial space is stable (strongly stable) or, equivalently, that the monomial space \( \langle G(I) \rangle \), where \( G(I) \) is the unique minimal set of monomial generators of \( I \), is stable (strongly stable).

On the monomials, unless we explicitly say differently, we use a degree lexicographical order with respect to the ordering of the variables \( x_1 > x_2 > \cdots > x_n \). A monomial space \( V \subset S \) is called a lexsegment if, for all \( d \in \mathbb{N} \), there exists a monomial \( u \in S_d \) (the degree \( d \) part of \( S \)) such that

\[ V \cap S_d = \langle v \in S_d : v \geq u \rangle. \]

We will sometimes denote this by

\[ L_{\geq u} = \{ v \in S_d : v \geq u \}. \]

Clearly, a lexsegment monomial space is strongly stable. The celebrated theorem of Macaulay explains when a lexsegment monomial space is an ideal. We recall that
given a natural number \(a\) and a positive integer \(d\), the \(d\)th Macaulay representation of \(a\) is the unique writing
\[
a = \sum_{i=1}^{d} \binom{k(i)}{i}
\]
such that \(k(d) > k(d-1) > \cdots > k(1) \geq 0;
\]
see [BH] Lemma 4.2.6. Then
\[
a^{(d)} = \sum_{i=1}^{d} \binom{k(i) + 1}{i+1}.
\]

A numerical sequence \((h_i)_{i \in \mathbb{N}}\) is called an O-sequence if \(h_0 = 1\) and \(h_{d+1} \leq h_d^{(d)}\) for all \(d \geq 1\). (The reader should be careful because the definition of an O-sequence depends on the numbering: A vector \((m_1, \ldots, m_n)\) will be an O-sequence if \(m_1 = 1\) and \(m_{i+1} \leq m_i^{(i-1)}\) for all \(i \geq 2\).) The theorem of Macaulay (for example see [BH] Theorem 4.2.10]) says that, given a numerical sequence \((h_i)_{i \in \mathbb{N}}\), the following are equivalent:

(i) \((h_i)_{i \in \mathbb{N}}\) is an O-sequence with \(h_1 \leq n\).

(ii) There is a homogeneous ideal \(I \subset S\) such that \((h_i)_{i \in \mathbb{N}}\) is the Hilbert function of \(S/I\).

(iii) The lexsegment monomial space \(L \subset S\) such that \(L \cap S_d\) consists of the biggest \(\left(\frac{n+d-1}{d}\right) - h_d\) monomials is an ideal.

For any \(\mathbb{Z}\)-graded finitely generated \(S\)-module \(M\), there is a minimal graded free resolution,
\[
0 \to \bigoplus_{j \in \mathbb{Z}} S(-j)^{\beta_{p,j}(M)} \to \bigoplus_{j \in \mathbb{Z}} S(-j)^{\beta_{p-1,j}(M)} \to \cdots \to \bigoplus_{j \in \mathbb{Z}} S(-j)^{\beta_{0,j}(M)} \to M \to 0,
\]
where \(S(k)\) denotes the \(S\)-module \(S\) supplied with the new grading \(S(k)_i = S_{k+i}\). The celebrated Hilbert’s Syzygy theorem (for example see [BH] Corollary 2.2.14 (a)) guarantees \(p \leq n\). The natural numbers \(\beta_{i,j} = \beta_{i,j}(M)\) are numerical invariants of \(M\), and they are called the graded Betti numbers of \(M\). The coarser invariants \(\beta_i = \beta_i(M) = \sum_{j \in \mathbb{Z}} \beta_{i,j}\) are called the (total) Betti numbers of \(M\). A graded Betti number \(\beta_{i,i+d}\) is said to be extremal if \(\beta_{i,i+d} \neq 0\) and for all \((p,q) \neq (i,d)\) such that \(p \geq i\) and \(q \geq d\), \(\beta_{p,p+q} = 0\). We will refer to the matrix \((\beta_{i,j})\) as the Betti table of \(M\). Actually, in the situations we will consider in this paper, \(M = I\) is a homogeneous ideal of \(S\). In this case \(\beta_{i,j} = 0\) whenever \(i \geq n\) or \(j \leq i\) (unless \(I = S\)). We will present the Betti table of \(I\) as follows:
\[
\begin{pmatrix}
\beta_{0,1} & \beta_{1,2} & \beta_{2,3} & \cdots & \beta_{n-1,n} \\
\beta_{0,2} & \beta_{1,3} & \beta_{2,4} & \cdots & \beta_{n-1,n+1} \\
\beta_{0,3} & \beta_{1,4} & \beta_{2,5} & \cdots & \beta_{n-1,n+2} \\
\vdots & \vdots & \vdots & \cdots & \vdots
\end{pmatrix}
\]

Also, if the definition of the Betti table of \(M\) predicts infinite many rows, only a finite number of entries are not zero (because \(M\) is finitely generated). Consequently, only a finite number of rows are significant, and in the examples we will present throughout the paper we will draw just the significant rows. Notice that a graded Betti number is extremal if and only if it is the nonzero top left “corner” in a block of zeroes of the Betti table.
For an integer \( d \), the \( S \)-module \( M \) is said to have a \( d \)-linear resolution if \( \beta_{i,j}(M) = 0 \) for every \( i = 0, \ldots, p \) and \( j \neq i + d \), or, equivalently, if \( \beta_i(M) = \beta_{i,i+d}(M) \) for any \( i = 0, \ldots, p \). Notice that if \( M \) has \( d \)-linear resolution, then it is generated in degree \( d \). The \( S \)-module \( M \) is said to be componentwise linear if \( M_{\langle d \rangle} \) has a \( d \)-linear resolution for all \( d \in \mathbb{Z} \), where \( M_{\langle d \rangle} \) means the \( S \)-submodule of \( M \) generated by the elements of degree \( d \) of \( M \). It is not difficult to show that if \( M \) has a linear resolution, then it is componentwise linear.

Let \( I \) be a stable monomial ideal. For all \( i \in \{1, \ldots, n\} \) and \( d \in \mathbb{N} \) we set

\[
m_{i,d}(I) = |\{u \text{ monomials in } G(I) \cap S_d : m(u) = i\}|,
m_i(I) = |\{u \text{ monomials in } G(I) : m(u) = i\}|.
\]

By the Eliahou-Kervaire formula [EK] (see also [HH2, Corollary 7.2.3]) we have

\[
\beta_{i,i+d}(I) = \sum_{k=i}^{n} \binom{k-1}{i} m_{k,d}(I).
\]

It is convenient to introduce the analog of the \( m_{i,d} \)'s for all \( \mathbb{Z} \)-graded finitely generated \( S \)-module \( M \): To this aim, for all \( i \in \{1, \ldots, n+1\} \) and \( d \in \mathbb{Z} \) we set

\[
m_{i,d}(M) = \sum_{k=0}^{n} (-1)^{k-i+1} \binom{k}{i-1} \beta_{k,k+d}(M).
\]

The following lemma shows that knowing the \( m_{i,d}(M) \)'s is equivalent to knowing the Betti table of \( M \), and that the two definitions agree when \( M = I \) is a stable ideal.

**Lemma 1.1.** Let \( M \) be a \( \mathbb{Z} \)-graded finitely generated \( S \)-module. Then

\[
\beta_{i,i+d}(M) = \sum_{k=i}^{n+1} \binom{k-1}{i} m_{k,d}(M).
\]

**Proof.** Set \( m_{k,d} = m_{k,d}(M) \) and \( \beta_{i,j} = \beta_{i,j}(M) \). By the definition of the \( m_{k,d} \)'s we have the following identity in \( \mathbb{Z}[t] \):

\[
\sum_{k=1}^{n+1} m_{k,d} t^{k-1} = \sum_{i=0}^{n} \beta_{i,i+d}(t-1)^i.
\]

Replacing \( t \) by \( s + 1 \), we get the identity of \( \mathbb{Z}[s] \):

\[
\sum_{k=1}^{n+1} m_{k,d} (s + 1)^{k-1} = \sum_{i=0}^{n} \beta_{i,i+d} s^i,
\]

which implies the lemma. \( \square \)

Let us define also the coarser invariants:

\[
m_i(M) = \sum_{d \in \mathbb{Z}} m_{i,d}(M) \quad \forall \ i = 1, \ldots, n + 1.
\]
2. Graded Betti numbers of componentwise linear ideals

In this section we want to discuss the problem of characterizing the graded Betti numbers of a componentwise linear ideal $I \subset S = K[x_1, \ldots, x_n]$. This is a difficult task. In fact, we are not going to solve the problem; rather we are going to explain why it is problematic. Such an issue is equivalent to characterize the possible graded Betti numbers of a strongly stable monomial ideal of $S$. In fact, in characteristic 0 this is true because the generic initial ideal of any ideal $I$ is strongly stable [Ei, Theorem 15.23]. Moreover, if $I$ is componentwise linear and the term order is degree reverse lexicographic, then the graded Betti numbers of $I$ are the same of those of $\text{Gin}(I)$ by a result of Aramova, Herzog and Hibi [AHH]. In positive characteristic it is still true that for a degree reverse lexicographic order the graded Betti numbers of $I$ are the same of those of $\text{Gin}(I)$, provided that $I$ is componentwise linear. But in this case $\text{Gin}(I)$ might be not strongly stable. However, it is known that if we start from a componentwise linear ideal, it is stable (see Conca, Herzog and Hibi [CHH, Lemma 1.4]). The graded Betti numbers of a stable ideal do not depend on the characteristic because of the Eliahou-Kervaire formula (3). So to compute the graded Betti numbers of $\text{Gin}(I)$ we can assume characteristic 0. Let us call $J$ the ideal $\text{Gin}(I)$ viewed in characteristic 0. The ideal $J$, being stable, is componentwise linear, so we are done by what we have said above. Summarizing, we showed:

**Proposition 2.1.** The following sets coincide:

1. $\{\text{Betti tables } (\beta_{i,j}(I)) \mid I \subset S \text{ is componentwise linear}\}$;
2. $\{\text{Betti tables } (\beta_{i,j}(I)) \mid I \subset S \text{ is strongly stable}\}$.

Before beginning the discussion on graded Betti numbers, it is worthwhile to notice that to characterize the total Betti numbers of a componentwise linear ideal is an easy task. Indeed, together with Proposition 2.1, the following remark of Murai yields the answer:

**Remark 2.2 (Murai).** Let $(m_1, \ldots, m_n)$ be a sequence of natural numbers. The following are equivalent:

1. $m_1 = 1$ and $m_{i+1} = 0$ whenever $m_i = 0$.
2. There exists a strongly stable ideal $I \subset S$ such that $m_i(I) = m_i$ for any $i = 1, \ldots, n$.

That (ii) $\implies$ (i) is very easy to show. For the reverse implication, given a sequence $(m_1, \ldots, m_n)$ satisfying (i), set $k = \max\ell\{m_\ell \neq 0\}$. By assumption we have $m_i \geq 1$ for all $i = 1, \ldots, k$; therefore it makes sense to define the following monomial spaces for each $j = 1, \ldots, k - 1$:

$$V_j = \left\langle \prod_{i=1}^{j-2} x_i^{m_i+1-1} \cdot x_j^{m_j-1} \cdot x_{j+1}^{m_{j+1}}, \prod_{i=1}^{j-2} x_i^{m_i+1-1} \cdot x_j^{m_j-2} \cdot x_{j+1}^{m_{j+1}+1}, \ldots, \prod_{i=1}^{j-2} x_i^{m_i+1-1} \cdot x_j^{m_j+m_{j+1}+1} \right\rangle.$$

We also define

$$V_k = \left\langle \prod_{i=1}^{k-2} x_i^{m_i+1-1} \cdot x_k^{m_k-1} \cdot x_k, \prod_{i=1}^{k-2} x_i^{m_i+1-1} \cdot x_k^{m_k-2} \cdot x_k^2, \ldots, \prod_{i=1}^{k-2} x_i^{m_i+1-1} \cdot x_k^{m_k} \right\rangle.$$
Clearly, for all $j = 1, \ldots, k$, we have $w_i(V_j) = m_j$ if $i = j$ and $w_i(V_j) = 0$ otherwise. Set

$$I = \left( \bigoplus_{j=1}^{k} V_k \right) \subset S.$$ 

It is easy to see that $I$ is a strongly stable monomial ideal and that $\langle G(I) \rangle = \bigoplus_{j=1}^{k} V_k$, so we get (ii).

Actually, the possible Betti numbers of an ideal with linear resolution are also known. Proposition 2.1 and [Mu, Proposition 3.8] yield the following:

**Proposition 2.3.** Let $m_1, \ldots, m_n$ be a sequence of natural numbers. Then the following are equivalent:

1. There exists a homogeneous ideal $I \subset S$ with $d$-linear resolution such that $m_k(I) = m_k$ for all $k = 1, \ldots, n$.
2. $(m_1, \ldots, m_n)$ is an $O$-sequence such that $m_2 \leq d$; that is:
   a. $m_1 = 1$,
   b. $m_2 \leq d$,
   c. $m_{i+1} \leq m_i^{(i-1)}$ for any $i = 2, \ldots, n - 1$.

**Discussion 2.4.** In [Mu, Proposition 3.8] is shown the equivalence between point (2) of Proposition 2.3 and the existence of a strongly stable ideal $I \subset S$ generated in degree $d$ such that $m_k(I) = m_k$ for all $k = 1, \ldots, n$. Looking carefully at the proof, one can see that, given an $O$-sequence $(m_1, \ldots, m_n)$, a special strongly stable ideal $I \subset S$ such that $m_k(I) = m_k$ shows up. This special strongly stable ideal, which we are going to define more explicitly, will play a crucial role throughout the paper.

Given an $O$-sequence $(m_1, \ldots, m_n)$ such that $m_2 \leq d$, set

$$V_i = \{ \text{biggest } m_i \text{ monomials } u \in S_d \text{ such that } m(u) = i \}$$

for all $i = 1, \ldots, n$. Then the discussed ideal is

$$I = \left( \bigcup_{i=1}^{n} V_i \right) \subset S.$$ 

We will refer to $I$ as the piecewise lexsegment monomial ideal (of type $(d, (m_1, \ldots, m_n))$). From what we have said above, it follows that the piecewise lexsegment of type $(d, (m_1, \ldots, m_n))$ is strongly stable if and only if $(m_1, \ldots, m_n)$ is an $O$-sequence such that $m_2 \leq d$.

Let $I \subset S$ be a strongly stable monomial ideal. Notice that both $I(j)$ and $mI$, where $j$ is a natural number and $m = (x_1, \ldots, x_n)$ is the graded maximal ideal of $S$, are strongly stable. For all $j \in \mathbb{N}$ and $i = 1, \ldots, n$, we define

$$\mu_{i,j}(I) = m_i(I(j)).$$ 

The entries of the matrix $(m_{i,j}(I))$ are uniquely determined by the ones of $(\mu_{i,j}(I))$, and vice versa. Indeed, if $J \subset S$ is a strongly stable monomial ideal, then for all $i = 1, \ldots, n$:

$$m_i(mJ) = \sum_{q=1}^{i} m_q(J).$$
Therefore we have the formula

\[ m_{i,j}(I) = m_i(I_{(j)}) - m_i(mI_{(j-1)}) = \mu_{i,j}(I) - \sum_{q=1}^{i} \mu_{q,j-1}(I) \]

which implies that we can pass from the \( \mu_{i,j} \)'s to the \( m_{i,j} \)'s. It also follows from this formula that we can do the converse path by induction on \( j \), because \( \mu_{i,d}(I) = m_{i,d}(I) \) if \( d \) is the smallest degree in which \( I \) is not zero. Therefore, using Proposition 2.1 to characterize the possible Betti tables of the componentwise linear ideals is equivalent to answering the following question:

**Question 2.5.** What are the possible matrices \( M(I) = (\mu_{i,j}(I)) \) where \( I \subset S \) is a strongly stable ideal?

We will refer to \( M = M(I) \) as the *matrix of generators* of the strongly stable ideal \( I \). We will feature \( M \) as follows:

\[
M = \begin{pmatrix}
\mu_{1,1} & \mu_{2,1} & \mu_{3,1} & \ldots & \mu_{n,1} \\
\mu_{1,2} & \mu_{2,2} & \mu_{3,2} & \ldots & \mu_{n,2} \\
\mu_{1,3} & \mu_{2,3} & \mu_{3,3} & \ldots & \mu_{n,3} \\
\vdots & \vdots & \vdots & \ldots & \vdots \\
0 & 0 & 0 & \ldots & 0 \\
1 & d & 0 & 0 & 0 \\
1 & d+1 & d+1 & k & \\
\end{pmatrix}
\]

We can immediately state the following:

**Proposition 2.6.** Let \( M = (\mu_{i,j}) \) be the matrix of generators of a strongly stable monomial ideal \( I \subset S \). Then the following conditions hold:

(i) Each nonzero row vector \((\mu_{1,j}, \mu_{2,j}, \ldots, \mu_{n,j})\) of \( M \) is an \( O \)-sequence such that \( \mu_{2,j} \leq j \).

(ii) For all \( i \) and \( j \) one has \( \mu_{i,j} \geq \sum_{q=1}^{i} \mu_{q,j-1} \).

**Proof.** Condition (i) follows from Proposition 2.3 since \( I_{(j)} \) has a \( j \)-linear resolution for all \( j \) greater than or equal to the lower degree in which \( I \) is not zero. Condition (ii) follows from (7). \( \square \)

Notice that the Noetherianity of \( S \) (or, if you prefer, conditions (i) and (ii) of Proposition 2.6) implies that there exists \( m \in \mathbb{N} \) such that \( \mu_{i,j}(I) = \sum_{q=1}^{i} \mu_{q,j-1}(I) \) for all \( j > m \) and \( i \in \{1, \ldots, n\} \). So, though \( M \) has infinitely many rows, the relevant ones are just a finite number, and in the examples we will write just them.

One may expect that the conditions described in Proposition 2.6 are sufficient. But this is not the case at all.

**Example 2.7.** One obstruction is illustrated already by Remark 2.2. Consider the matrix

\[
M = \begin{pmatrix}
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
1 & d & 0 & 0 \\
1 & d+1 & d+1 & k \\
\end{pmatrix}
\]

where the first nonzero row from the top is the \( d \)th and \( d+1 < k \leq (d+1)^{(2)} \). Such a matrix clearly satisfies the necessary conditions of Proposition 2.6. However, if there existed a strongly stable ideal \( I \subset K[x_1, x_2, x_3, x_4] \) with matrix of generators \( M \),
then it would satisfy $m_1(I) = 1$, $m_2(I) = d$, $m_3(I) = 0$ and $m_4(I) = k - d - 1 > 0$.

The first matrix of this kind is

$$
M = \begin{pmatrix}
0 & 0 & 0 & 0 \\
1 & 2 & 0 & 0 \\
1 & 3 & 3 & 4
\end{pmatrix}.
$$

The explained obstruction gives rise to a class of counterexamples. However, such a class does not fill the gap between the existence of a strongly stable ideal with matrix of generators $M$ and the necessary conditions of Proposition 2.6. Let us look at the following matrix:

$$
M = \begin{pmatrix}
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
1 & 3 & 2 & 2 \\
1 & 4 & 6 & 9
\end{pmatrix}.
$$

One can check that the necessary conditions described in Proposition 2.6 hold. However one can show that there is no strongly stable monomial ideal $I \subset K[x_1, \ldots, x_4]$ with $M$ as a matrix of generators. Notice that such an ideal would have $m_1(I) = 1$, $m_2(I) = 3$, $m_3(I) = 2$ and $m_4(I) = 3$, which does not contradict Remark 2.2.

**Example 2.8.** Obviously the property of having linear resolution can be detected by looking at the graded Betti numbers. In the following example we show that this is no longer true for componentwise linear ideals, and this strengthens the impression that to give a complete characterization of the possible graded Betti numbers of a componentwise linear ideal is probably a hard task. More precisely, we are going to exhibit two ideals $I$ and $J$, one componentwise linear and one not, with the same Betti tables. This answers negatively a question raised in [NR, Question 1.1].

Consider the ideals of $K[x_1, x_2, x_3]$:

$$
I = (x_1^4, x_1^3 x_2, x_1^2 x_2^2, x_1 x_2 x_3^2, x_2^4, x_1^3 x_3, x_1^2 x_2 x_3, x_1 x_3^3, x_1 x_2^2 x_3^2)
$$

and

$$
J = (x_1^4, x_1^3 x_2, x_1^2 x_2^2, x_1 x_2^2 x_3, x_1 x_2 x_3^2, x_1 x_2 x_3, x_1^4, x_1^2 x_3^2, x_2^4 x_3).
$$

Notice that $I$ and $J$ are generated in degrees 4 and 5. By CoCoA [Co] one can check that $I$ and $J$ have the same Betti table, namely:

$$
\begin{pmatrix}
0 & 0 & 0 \\
0 & 0 & 0 \\
6 & 6 & 1 \\
3 & 6 & 3
\end{pmatrix}.
$$

One can easily check that $I$ is strongly stable, so in particular it is componentwise linear. On the contrary, $J$ is not componentwise linear, since $J_{(4)} = (x_1^4, x_1^3 x_2, x_1^2 x_2^2, x_1^2 x_3, x_1 x_2^2 x_3, x_1 x_2 x_3^2)$, as one can check by CoCoA, does not have a 4-linear resolution.

We are going to explain some reasons why the conditions of Proposition 2.6 for a matrix $M$ are in general not sufficient to have a strongly stable ideal corresponding to it. By the discussion after Proposition 2.3, we know that for a given sequence...
Let $J$ be the ideal of type $(d, \mu(\mu_1, \ldots, \mu_n))$. If $J$ is not strong stable, then $J = J_1 \cup J_2$. If $J_1$ is strongly stable, then $J_1 = I$. If $J_2$ is strongly stable, then $J_2 = \emptyset$. Therefore, $J = I$. By Proposition 2.9, $J$ is the monomial ideal of type $(d, \mu(\mu_1, \ldots, \mu_n))$, and $J$ is the piecewise lexsegment of type $(d, \mu(\mu_1, \ldots, \mu_n))$. Therefore, $J = I$.
Observe that $T(j + 1)$ is a piecewise lexsegment ideal of type $(j + 1, (\mu_{1,j+1}, \ldots, \mu_{n-1,j+1}, a))$, where $a \leq \mu_{n,j+1}$. Since $(\mu_{1,j+1}, \ldots, \mu_{n-1,j+1}, a)$ is an $O$-sequence with $\mu_{2,j+1} \leq j + 1$, it follows that $T(j + 1)$ is strongly stable by the discussion after Proposition 2.3. Thus for each $1 \leq k < i \leq n$ such that $x_i|u$, we have that $(u/x_i)x_k \in T(j + 1) \subset I(j + 1)$.

**Corollary 2.10.** Let $M = (\mu_{i,j})$ be a matrix with 3 columns. Then $M$ is the matrix of generators of a strongly stable monomial ideal $I \subset K[x_1, x_2, x_3]$ if and only if the following conditions hold:

1. Each nonzero row vector $(\mu_{1,j}, \mu_{2,j}, \mu_{3,j})$ of $M$ is an $O$-sequence with $\mu_{2,j} \leq j$.
2. For all $j \in \mathbb{N}$ one has $\mu_{2,j} \geq \mu_{1,j-1} + \mu_{2,j-1}$ and $\mu_{3,j} \geq \mu_{1,j-1} + \mu_{2,j-1} + \mu_{3,j-1}$.

**Proof.** The conditions are necessary from Proposition 2.6. Furthermore, since an ideal $I \subset K[x_1, x_2]$ generated in one degree is a piecewise lexsegment if and only if it is strongly stable, we automatically have condition (3) of Proposition 2.9.

Although the complete characterization of the matrix of generators of an arbitrary strongly stable ideal seems to be very complicated, based on the fact that the lexsegment property of an ideal is preserved under multiplication by the maximal ideal $m$, one may expect a characterization for the matrix of generators of lexsegment ideals. To answer this question, first we define the concept of a $d$-lex sequence.

**Definition 2.11.** A sequence of nonnegative integers $m_1, \ldots, m_n$ is called a $d$-lex sequence if there exists a lexsegment ideal $L \subset S$ generated in degree $d$ such that $m_i(L) = m_i$ for all $i$.

Because of the fact that if $I \subset S$ is a lexsegment ideal, then $mI$ is still a lexsegment ideal, we clearly have that $M = (\mu_{i,j})$ is the matrix of generators of a lexsegment ideal if and only if the following conditions hold:

1. Each nonzero row vector $(\mu_{1,j}, \mu_{2,j}, \ldots, \mu_{n,j})$ of $M$ is a $j$-lex sequence.
2. For all $i$ and $j$ one has $\mu_{i,j} \geq \sum_{q=1}^{i} \mu_{q,j-1}$.

Therefore to characterize the matrix of generators of lexsegment ideals we need to characterize arbitrary $d$-lex sequences. To do this, we have to recall the definition of the natural decomposition of the complement set of monomials belonging to a lexsegment ideal generated in a fixed degree. In what follows we denote by $[x_t, \ldots, x_n]_r$ ($1 \leq t \leq n$) the set of all monomials of degree $r$ in the variables $x_t, \ldots, x_n$.

**Definition 2.12.** Let $u = x_{j(1)} \cdots x_{j(d)} \in S_d$ ($1 \leq j(1) \leq \cdots \leq j(d)) \leq n$) be a monomial and set $L_{<u} = \{v \in S_d \mid v < u\}$. Following the method described in [BH, page 159] (where $L_{<u}$ is denoted by $L_u$), we can partition the set $L_{<u}$ as

$$L_{<u} = \bigcup_{i=1}^{d} [x_{j(i)+1}, \ldots, x_n]_{d-i+1} \cdot x_{j(1)} \cdots x_{j(i-1)},$$

which is called the natural decomposition of $L_{<u}$.

Before proving the next result, notice that the powers of the maximal ideal are lexsegment ideals, and the following formula holds for their $d$-lex sequences:

$$m_i(m^d) = \binom{i+d-2}{d-1}.$$  

**Proposition 2.13.** Let $m_1, \ldots, m_n$ be a sequence of natural numbers and let $\mu = \sum_{i=1}^n m_i$. Suppose that

$$\ell = \binom{n+d-1}{d} - \mu = \sum_{j=1}^d \binom{k(j)}{j}$$

is the $d$-th Macaulay representation of $\ell$. Then $m_1, \ldots, m_n$ is a $d$-lex sequence if and only if

$$m_i = \binom{i+d-2}{d-1} - \sum_{j=1}^d \binom{k(j)-n+i-1}{j-1}.$$  

**Proof.** The sequence $m_1, \ldots, m_n$ is a $d$-lex sequence if and only if $I_u = (L_{\geq u})$ satisfies $m_i(I_u) = m_i$ for all $i = 1, \ldots, n$, where $u$ is the $\mu$th biggest monomial of degree $d$. Let us write $u = x_{j(1)} \cdots x_{j(d)}$, $1 \leq j(1) \leq \cdots \leq j(d) \leq n$. By the natural decomposition of $L_{<u}$ we have

$$\ell = |L_{<u}| = \sum_{p=1}^d \dim K[x_{j(i)+1}, \ldots, x_n]_{d-p+1} = \sum_{p=1}^d \binom{n-j(p)+d-p}{d-p+1}.$$  

Setting $t = d - i + 1$ and $k(t) = n - j(d-t+1) + t - 1$, we have that $\sum_{t=1}^d \binom{k(t)}{t}$ is the $d$th Macaulay representation of $\ell$. The natural decomposition of $L_{<u}$ and (8) show that

$$m_i((L_{<u})) = \sum_{t=1}^d m_i(x_{j(d-t+1)+1}, \ldots, x_n)^t = \sum_{t=1}^d \binom{i-j(d-t+1)+t-2}{t-1} = \sum_{t=1}^d \binom{k(t)-n+i-1}{t-1}.$$  

Because

$$m_i(I_u) = m_i(m^d) - m_i((L_{<u})),$$

we get the conclusion thanks to (8). \qed

We recall that a homogeneous ideal $I \subset S$ is said to be Gotzmann if the number of minimal generators of $mI_{(j)}$ is the smallest possible for every $j \in \mathbb{N}$, namely is equal to

$$\binom{n+j}{j+1} - \binom{n+j-1}{j} - \mu_j \binom{j}{j},$$

where $\mu_j$ is the number of minimal generators of $I_{(j)}$. The graded Betti numbers of a Gotzmann ideal coincide with its associated lexsegment ideal; see [HHH]. Therefore Proposition 2.13 also characterizes the graded Betti numbers of Gotzmann ideals.

### 3. The Possible Extremal Betti Numbers of a Graded Ideal

For a fixed $\ell \in \{1, \ldots, n\}$, $d \in \mathbb{N}$ and $k \leq (\ell+d-2)$, we denote by $u(\ell, k, d)$ the $k$th biggest monomial $u \in S_d$ such that $m(u) = \ell$ or, equivalently, $x_{\ell}$ times the $k$th biggest monomial in $K[x_1, \ldots, x_\ell]_{d-1}$. By $U(\ell, k, d)$ we denote the ideal of $S$ generated by the set $L_{\geq u(\ell, k, d)} \cap K[x_1, \ldots, x_\ell]$. Notice that $U(\ell, k, d)$ is not a lexsegment in $S$. However, it is the extension of a lexsegment in $K[x_1, \ldots, x_\ell]$.  

Furthermore, $U(\ell, k, d)$ is obviously a piecewise lexsegment in $S$. In this section we need to introduce the following definition: A monomial ideal $I \subset S$ generated in one degree is called a piecewise lexsegment up to $\ell$ if $I \cap K[x_1, \ldots, x_\ell] \subset K[x_1, \ldots, x_\ell]$ is a piecewise lexsegment.

**Remark 3.1.** Notice that for all $q \in \mathbb{N}$, denoting by $m \subset S$ the maximal irrelevant ideal, $m^q U(\ell, k, d) \cap K[x_1, \ldots, x_\ell]$ is equal to $U(\ell, m_\ell(m^q U(\ell, k, d), d + q) \cap K[x_1, \ldots, x_\ell]$. In particular, $m^q U(\ell, k, d)$ is a piecewise lexsegment up to $\ell$.

**Lemma 3.2.** The ideal $U(\ell, k, d) \subset S$ is the smallest strongly stable ideal containing the biggest $k$ monomials $u_i \in S_d$ such that $m(u_i) = \ell$ for all $i = 1, \ldots, k$.

**Proof.** Let $J \subset S$ be the smallest strongly stable ideal containing the biggest $k$ monomials $u_i \in S_d$ such that $m(u_i) = \ell$ for all $i = 1, \ldots, k$. Being the extension of a lexsegment, $U(\ell, k, d)$ is strongly stable, so that $J \subset U(\ell, k, d)$. Therefore, let us show the inclusion $U(\ell, k, d) \subset J$. Let $u$ be a minimal monomial generator of $U(\ell, k, d)$. So $u$ has degree $d$ and $m(u) \leq \ell$. Actually, we can assume $m(u) < \ell$; otherwise there is nothing to prove. So let us write

$$u = x_1^{a_1} \cdots x_{\ell-1}^{a_{\ell-1}}.$$

By definition $u > u(\ell, k, d) = x_1^{b_1} \cdots x_\ell^{b_\ell}$. Set $F = \{ i : a_i > b_i \}$. Because $u > u(\ell, k, d)$, we have $F \neq \emptyset$ and $a_j = b_j$ for all $j < i_0 = \min \{ i : i \in F \}$. If $|F| = 1$, then $a_i = b_i$ for all $i_0 < i < \ell$ and $b_\ell = a_{i_0} - b_{i_0}$, so that $u = x_{i_0}^{a_{i_0} - b_{i_0}}(u(\ell, k, d)/x_{i_0}^{a_{i_0} - b_{i_0}}) \in J$. If $|F| > 1$, take $j > i_0$ such that $a_j > b_j$. The monomial $u' = x_\ell \cdot (u/x_j)$ is such that $u' > u(\ell, k, d)$ and $m(u') = \ell$. Therefore $u' \in J$, so that $u = x_j \cdot (u'/x_\ell)$ belongs to $J$ too.

The above lemma allows us to characterize the possible extremal Betti numbers of a homogeneous ideal in a polynomial ring. To this aim, we start with a discussion. To $U(\ell, k, d)$ we can associate the numerical sequence $(m_1, \ldots, m_\ell)$ where $m_i = m_i(U(\ell, k, d))$. Notice that $m_\ell = k$. By the discussion after Proposition 2.3 if $V$ is a strongly stable monomial ideal generated in degree $d$ such that $m_\ell(V) = k$, then there must exist a strongly stable piecewise lexsegment ideal $U$ such that $m_i(U) = m_i(V)$, which contains the biggest monomials $u \in S_d$ such that $m(u) = \ell$. By Lemma 3.2 $U(\ell, k, d) \subset U$, so that $m_i \leq m_i(V)$ for all $i$. It is possible to characterize the possible numerical sequences like these. To this purpose, we need to introduce a notion. Given a natural number $a$ and a positive integer $d$, consider the $d$th Macaulay representation of $a$, say $a = \sum_{i=1}^{d} \binom{k(i)}{i}$. For all integer numbers $j$, we set

$$a^{(d,j)} = \sum_{i=1}^{d} \binom{k(i) + j}{i + j},$$

where we put $\binom{p}{q} = 0$ whenever $p$ or $q$ are negative, and $\binom{0}{0} = 1$. Notice that $a^{(d,0)} = a$ and $a^{(d,1)} = a^{(d)}$.

**Lemma 3.3.** If $k \leq \binom{\ell + d - 2}{\ell - 1}$, then

$$m_i(U(\ell, k, d)) = k^{\ell - 1, i - \ell} \forall i = 1, \ldots, \ell.$$

Furthermore, if $i \geq 2$, then $k^{\ell - 1, i - \ell} = \min \{ a : k \leq a^{(i - 1, \ell - i)} \}$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
Thus \((\ell - 1)\)th Macaulay representation of \(k\), namely \(k = \sum_{j=1}^{\ell-1} \binom{k(j)}{j}\). So

\[
b = k^{(\ell-1,i-\ell)} = \sum_{j=\ell-i+1}^{\ell-1} \binom{k(j) + i - \ell}{j + i - \ell}.
\]

If \(\max\{j : k(j) < j\} \geq \ell - i\), then the above representation is the \((i - 1)\)th Macaulay representation of \(b\). Therefore \(b^{(i-1,\ell-i)} = k\), so the statement is obvious in this case.

Thus we can assume that \(\max\{j : k(j) < j\} < \ell - i\). In particular, \(k(\ell - i) \geq \ell - i\), so that the \((i - 1)\)th Macaulay representation of \(b - 1\) is

\[
b - 1 = \sum_{j=\ell-i+1}^{\ell-1} \binom{k(j) + i - \ell}{j + i - \ell}.
\]

Thus \((b - 1)^{(i-1,\ell-i)} = \sum_{j=\ell-i+1}^{\ell-1} \binom{k(j)}{j}\), which in this case is smaller than \(k\). So \(b \leq \min\{a : k \leq a^{(i-1,\ell-i)}\}\). On the other hand, let us consider the \((i - 1)\)th Macaulay representation of \(b\), namely \(b = \sum_{j=1}^{i-1} \binom{h(j)}{j}\). By [BH, Lemma 4.2.7], we infer the inequality

\[
(h(i - 1), \ldots, h(1)) > (k(\ell - 1) + i - \ell, \ldots, k(\ell - i + 1) + i - \ell)
\]

in the lexicographical order. Of course the inequality stays true when shifting \(\ell - i\), namely

\[
(h(i - 1) + \ell - i, \ldots, h(1) + \ell - i) > (k(\ell - 1), \ldots, k(\ell - i + 1))
\]

in the lexicographical order. Again using [BH, Lemma 4.2.7], we deduce that \(b^{(i-1,\ell-i)} > k\). So \(b \geq \min\{a : k \leq a^{(i-1,\ell-i)}\}\), which concludes this part.

Let us prove that

\[
m_i(U(\ell, k, d)) = k^{(\ell-1,i-\ell)} \quad \forall \, i = 1, \ldots, \ell.
\]

The condition \(k \leq (\ell + d - 1)\) assures that we can construct \(V = U(\ell, k, d)\). The equality is true for \(i = 1\), because \(k^{(\ell-1,1-\ell)} = 1\). From Proposition 2.3 we have, for all \(i = 2, \ldots, \ell:\)

\[
m_{i+1}(V) \leq m_i(V)^{i-1}, \quad m_{i+2}(V) \leq m_{i+1}(V)^{i}, \ldots, \quad k = m_{\ell}(V) \leq m_{\ell-1}(V)^{(\ell-2)}.
\]

Putting together the above inequalities, we get

\[
k \leq m_i(V)^{(i-1,\ell-i)}.
\]

From this and what was proved above we deduce that

\[
m_i(V) \geq k^{(\ell-1,i-\ell)}.
\]

From the above argument and the discussion following Proposition 2.3 it is clear that a piecewise lexsegment monomial space \(W \subset S_d\) with \(m_i(W) = k^{(\ell-1,i-\ell)} \forall \, i = 1, \ldots, \ell\) must exist. We have \(V \subset W\) by Lemma 3.2 so we also get the inequality

\[
m_i(V) \leq k^{(\ell-1,i-\ell)}.
\]

\[\square\]
We introduce the function $T : \mathbb{N}^r \to \mathbb{N}^r$ such that $T(v) = (v_1, v_1 + v_2, \ldots, v_1 + v_2 + \cdots + v_r)$, where $v = (v_1, \ldots, v_r)$. Furthermore, we define $S_q(v)$ as the last entry of $T^q(v)$.

**Remark 3.4.** The significance of the above definition is the following: Let $I \subset S = K[x_1, \ldots, x_n]$ be a stable ideal generated in one degree. One can easily show that for all $q \in \mathbb{N}$ and $i \in \{1, \ldots, n\}$,

$$S_q((m_1(I), m_2(I), \ldots, m_i(I))) = m_i(m^qI).$$

Notice that we can also rephrase the second condition of Proposition 2.6 as

$$\mu_{i,j} \geq S_1((\mu_{1,j-1}, \mu_{2,j-1}, \ldots, \mu_{i,j-1})).$$

**Example 3.5.** In the next theorem the functions $S_q$ will play a crucial role. Especially, using Remark 3.3, Lemma 3.3 and Remark 3.1, one has

$$S_q((k^{(\ell-1,1-)}, k^{(\ell-1,2-)}, \ldots, k^{(\ell-1,i-)})) = S_q((m_1(U(\ell, k, d)), m_2(U(\ell, k, d)), \ldots, m_i(U(\ell, k, d)))) = m_i(m^qU(\ell, k, d)) = m_i(U(\ell, m_1U(\ell, k, d), d + q)) = S_q((k^{(\ell-1,1-)}, k^{(\ell-1,2-)}, \ldots, k))^{(\ell-1,i-)}.$$

Notice that the first time, $S_q$ is applied to a vector in $\mathbb{N}^i$, whereas the last time it is applied to a vector in $\mathbb{N}^q$.

Let $I$ be a homogeneous ideal of $S$ and $\beta_{i,j} = \beta_{i,j}(I)$ its graded Betti numbers. Let the extremal Betti numbers of $I$ be

$$\beta_{i_1, i_1+j_1}, \beta_{i_2, i_2+j_2}, \ldots, \beta_{i_k, i_k+j_k}.$$

Notice that $k < n$, and up to a reordering we can assume $0 < i_1 < i_2 < \cdots < i_k < n$ and $j_1 > j_2 > \cdots > j_k \geq 0$. If $I$ is a stable ideal, then, exploiting the Eliahou-Kervaire formula, one can check that $\beta_{i,i+j}(I)$ is extremal if and only if $m_{i+1,j}(I) \neq 0$ and $m_{p+q}v(I) = 0$ for all $(p, q) \neq (i, j)$ such that $p \geq i$ and $q \geq j$. In this case, moreover, we have $\beta(i,j+1) = m_{i+1,j}(I)$. Before showing the main result of the paper, we introduce the following concept.

**Definition 3.6.** Let $i = (i_1, \ldots, i_k)$ and $j = (j_1, \ldots, j_k)$ be such that $0 < i_1 < i_2 < \cdots < i_k < n$, $j_1 > j_2 > \cdots > j_k > 0$. We say that $I \subset S$ is a $(i,j)$-lex ideal if $I = \sum_{p=1}^k (L_p)$, where $L_p$ is a lexsegment ideal generated in degree $j_p$ in $K[x_1, \ldots, x_{i_p+1}]$.

**Theorem 3.7.** Let $i = (i_1, \ldots, i_k)$ and $j = (j_1, \ldots, j_k)$ be such that $0 < i_1 < i_2 < \cdots < i_k < n$ and $j_1 > j_2 > \cdots > j_k > 0$, and let $b_1, \ldots, b_k$ be positive integers. For all $p = 1, \ldots, k$ let

$$v^p = (b_p^{(j_p, -i_p)}, b_p^{(j_p, 1-i_p)}, \ldots, b_p^{(j_p, i_p-1-i_p)}) \in \mathbb{N}^{i_p+1-1}.$$

If $K$ has characteristic 0, then the following are equivalent:

(i) There is a homogeneous ideal $I \subset S$ with extremal Betti numbers $\beta_{i_p, i_p+j_p}(I) = b_p$ for all $p = 1, \ldots, k$.

(ii) There is a strongly stable ideal $I \subset S$ with extremal Betti numbers $\beta_{i_p, i_p+j_p}(I) = b_p$ for all $p = 1, \ldots, k$.  

(iv) There is an \((i,j)\)-lex ideal \(I \subset S\) with extremal Betti numbers \(\beta_{i_p,i_p+j_p}(I) = b_p\) for all \(p = 1, \ldots, k-1\).

Proof. (i) \(\iff\) (ii) follows by [BCP] Theorem 1.6. (iv) \(\implies\) (i) is obvious.

(ii) \(\implies\) (iii). By what was said before the theorem, we can replace \(\beta_{i_p,i_p+j_p}(I)\) by \(m_{i_p+1,j_p}(I)\) with \(m_{r+1,s}(I) = 0\) for all \((r,s) \neq (i_p,j_p)\) such that \(r \geq i_p\) and \(s \geq j_p\). Since \(m_{i_k+1,j_k}(I) = b_k\), we have

\[
b_k \leq \left( \frac{i_k + j_k - 1}{i_k} \right).
\]

We must have that

\[
m_{i_k+1+1}(m^{j_k-1-j_k}(I_{(j_k)})) + b_{k-1} = |\{\text{monomials } u \in I_{(j_k)} \cap S_{i_k-1} \text{ with } m(u) = i_k - 1\}| + |\{\text{monomials } u \in I_{j_k-1} \setminus I_{(j_k-1)} \text{ with } m(u) = i_k - 1\}| \leq |\{\text{monomials } u \in S_{i_k-1} \text{ with } m(u) = i_k - 1\}| = \left( \frac{i_k - 1 + j_k - 1}{i_k - 1} \right).
\]

From the discussion before the theorem, we also have

\[
m_i(I_{(j_k)}) \geq b_k^{(i_k,i_k-1)} \forall i \leq i_k.
\]

We eventually get

\[
m_{i_k-1+1}(m^{j_k-1-j_k}(I_{(j_k)})) \geq S_{j_k-1-j_k}(v^k).
\]

Putting together the above inequalities we obtain, for \(p = k - 1\),

\[
S_{j_p-1+j_p+1}(v^{p+1}) + b_p \leq \left( \frac{i_p + j_p - 1}{i_p} \right),
\]

and we can go on in the same way to show this for all \(p = 1, \ldots, k - 1\).

(iii) \(\implies\) (iv). If \(b_k \leq (i_k + j_k - 1)\), then we can form \(U(i_k + 1, b_k, j_k)\). Let us denote \(kI = U(i_k + 1, b_k, j_k)\). We have that

\[
m_{i_k+1+1}(kI_{(j_k-1)}) = S_{j_k-1-j_k}(v^k).
\]

From Remark 3.1, we deduce that

\[
(kI)_{(j_k-1)} \cap K[x_1, \ldots, x_{i_k+1}] = U(i_k+1, S_{j_k-1-j_k}(v^k), j_k-1) \cap K[x_1, \ldots, x_{i_k-1+1}].
\]

By the assumed numerical conditions, \(U(i_k+1, S_{j_k-1-j_k}(v^k) + b_{k-1}, j_k-1)\) exists and contains exactly \(b_{k-1}\) new monomials \(u\) such that \(m(u) = i_k - 1\). Therefore set

\[
k^{-1}I' = (U(i_k-1+1, S_{j_k-1-j_k}(v^k) + b_{k-1}, j_k-1))
\]

and

\[
k^{-1}I = kI + k^{-1}I'.
\]

By construction \(k^{-1}I\) is a \(((i_k-1, i_k), (j_k-1, j_k))\)-lex ideal with extremal Betti numbers \(\beta_{i_k-1,i_k+1+j_k}(k^{-1}I) = b_{k-1}\) and \(\beta_{i_k,i_k+j_k}(k^{-1}I) = b_k\). Continuing with the recursion we will end up with the desired \((i,j)\)-lex ideal \(I = 1I\). \(\square\)
Remark 3.8. For the reader who prefers the language of algebraic geometry, Theorem [3,7] can be used in the following setting: Let $X \subset \mathbb{P}^{n-1}$ be a projective scheme over a field of characteristic 0 and $\mathcal{I}_X$ its ideal sheaf. Then, by the graded version of Grothendieck’s local duality, $\beta_{i,i+d}$ is an extremal Betti number of the ideal $\bigoplus_{m \in \mathbb{N}} \Gamma(X, \mathcal{I}_X(m)) \subset S$ if and only if, setting $p = n - i - 1$ and $q = d - 1$:

1. $p \geq 1$;
2. $\dim_K(\mathcal{H}^p(X, \mathcal{I}_X(q-p))) = \beta_{i,i+d} \neq 0$.
3. $\mathcal{H}^r(X, \mathcal{I}_X(s-r)) = 0$ for all $(r,s) \neq (p,q)$ with $1 \leq r \leq p$ and $s \geq q$.

Example 3.9. Let us consider the following Betti table:

\[
\begin{pmatrix}
* & * & * & * & * & \cdots \\
* & * & * & 0 & 0 & \cdots \\
* & * & b & 0 & 0 & \cdots \\
0 & 0 & 0 & 0 & 0 & \cdots 
\end{pmatrix}
\]

Theorem [3,7] implies that there exists a homogeneous ideal in a polynomial ring (of characteristic 0) whose Betti table looks like the one above (where $a$ and $b$ are extremal) if and only if we are in one of the following cases:

(i) $a = 2$ and $b = 1, 2$;
(ii) $a = 1$ and $b = 1, 2, 3, 4$.

In fact, we have $b = \beta_{2,6}$ and $a = \beta_{3,5}$. Theorem [3,7] implies $a \leq 4$.

If $a = 2$, then the vector $\mathbf{v}^2 \in \mathbb{N}^3$ is

$\mathbf{v}^2 = (1, 2, 2)$.

Therefore $S_2(\mathbf{v}^2) = 8$, and Theorem [3,7] gives $8 + b \leq 10$. So we get $b = 1, 2$, as desired.

If $a = 1$, then the vector $\mathbf{v}^2 \in \mathbb{N}^3$ is

$\mathbf{v}^2 = (1, 1, 1)$.

So $S_2(\mathbf{v}^2) = 6$, and Theorem [3,7] yields $b = 1, 2, 3, 4$, as desired.

Eventually, if $a > 2$, a positive integer $b$ satisfying the conditions of Theorem [3,7] does not exist.

Acknowledgement

The authors are very grateful to the anonymous referee for suggesting point (iv) of Theorem [3,7] and the last statement in Lemma [3,3].
