Abstract

We consider a brane-universe in the background of an Anti-de Sitter/Schwarschild geometry. We show that the induced geometry of the brane is exactly given by that of a standard radiation dominated FRW-universe. The radiation is represented by a strongly coupled CFT with an \textit{AdS}-dual description. We show that when the brane crosses the horizon of the \textit{AdS}-black hole the entropy and temperature are simply expressed in the Hubble constant and its time derivative. We present formulas for the entropy of the CFT which are generally valid, and which at the horizon coincide with the FRW equations. These results shed new light on recently proposed entropy bounds in the context of cosmology.
1. Introduction

Recently the holographic principle was studied in a Friedmann-Robertson-Walker (FRW) universe filled with a conformal field theory (CFT) with a dual anti-de Sitter (AdS) description [1], see also [2–7]. An interesting and surprising relationship was found between the FRW equations controlling the cosmological expansion and the formulas that relate the energy and entropy of the CFT. The aim of the present paper will be to shed further light on this coincidence by studying the CFT/FRW-cosmology from a Randall-Sundrum type brane-world perspective [8,9].

Brane cosmology has previously been studied from an AdS/CFT perspective in [10,11]. Following these papers we describe the CFT dominated universe as a co-dimension one brane, with fixed tension, in the background of an AdS-black hole. In this description the movement of the brane turns out to be exactly described by the standard Friedmann equation in which the size of the universe directly corresponds to the distance of the brane to the center of the black hole. The brane starts out inside the black hole, it passes through the horizon and keeps expanding until it reaches a maximal radius, after which it recontracts and falls back into the black hole. From the AdS-perspective there are two special moments, one in the early and one in the late universe, when the brane crosses the horizon. The main goal of this paper is to show that at those moments the entropy density on the brane takes a special value given in terms of the Hubble constant and Newtons constant. Furthermore, at these times the Friedmann equation turns into an equation that expresses the entropy density in terms of the energy density and exactly coincides with a generalized form of the Cardy formula for the entropy of the CFT.

We begin by presenting the brane description of a CFT-dominated cosmology in section 2. The dimension \( d = n + 1 \) of the brane-universe will be taken to be arbitrary, but its relation with the dimension \( D = d+1 \) of the AdS space is of course fixed. In section 3 we argue that the radiation on the brane can be identified with the CFT dual to the AdS-space and use this fact to fix the normalization of Newtons constant and derive the FRW equations. The entropy density and temperature of the CFT at the moment that the brane crosses the horizon are calculated in section 4. We find that these quantities have a simple expression in terms of the Hubble constant and its time-derivative. In section 5 we derive the entropy formulas for the CFT and show the correspondence with the FRW equations. Finally, sections 6 and 7 contain some concluding remarks.

2. Brane cosmology

We consider an \((n+1)\)-dimensional brane with a constant tension in the background of an \((n+2)\)-dimensional AdS-Schwarzschild black hole. Following the AdS/CFT prescription [12,13] we regard the brane as the boundary of the AdS-geometry. An important difference is, however, that now the location and the metric on the boundary are, at least partly, dynamical. The movement of the brane is described by the boundary action

\[
\mathcal{L}_b = \frac{1}{8\pi G_N} \int_{\partial M} \sqrt{\gamma} \kappa + \frac{\kappa}{8\pi G_N} \int_{\partial M} \sqrt{\gamma}.
\]
Here $\mathcal{K} \equiv \mathcal{K}_{ij}^i$ is the trace of the extrinsic curvature, $\kappa$ is a parameter related to the tension of the brane, $G_N$ is the $(n+2)$-dimensional bulk Newton constant, $g$ is the determinant of the induced metric and $\partial \mathcal{M}$ denotes the surface of the brane. The equation of motion of the brane that follows from this Lagrangian is

$$K_{ij} = \frac{\kappa}{n} g_{ij}^{\text{induced}}.$$ (2)

This equation implies that $\partial \mathcal{M}$ is a surface of constant extrinsic curvature.

The bulk action is given by the $(n+2)$-dimensional Einstein action with cosmological term. The $AdS$-Schwarzschild metric provides a solution of the bulk equations of motion and can be written in the following form,

$$ds^2_{n+2} = \frac{1}{h(a)} da^2 - h(a) dt^2 + a^2 d\Omega^2_n,$$ (3)

$$h(a) = \frac{a^2}{L^2} + 1 - \frac{\omega_{n+1} M}{a^{n-1}},$$ (4)

where

$$\omega_{n+1} = \frac{16 \pi G_N}{n \text{Vol}(S^n)}.$$ (5)

In these equations, $L$ is the curvature radius of $AdS$. The pre-factor $\omega_{n+1}$ is chosen such that $M$ is the mass of the black hole as measured by an observer who uses $t$ as his time coordinate.

Our aim is to find the spherically symmetric solutions corresponding to a homogeneous and isotropic induced metric on the brane. Let us parameterize the location of the brane by giving $a$ as a function of the $AdS$-time $t$. Equivalently, we may introduce a new time parameter $\tau$ and specify the functions

$$a = a(\tau), \ t = t(\tau).$$ (6)

We will choose the time parameter $\tau$ such that the following relation is satisfied,

$$\frac{1}{h(a)} \left( \frac{da}{d\tau} \right)^2 - h(a) \left( \frac{dt}{d\tau} \right)^2 = -1.$$ (7)

This condition ensures that the induced metric on the brane takes the standard Robertson-Walker form,

$$ds^2_{n+1} = -d\tau^2 + a^2(\tau) d\Omega^2_n.$$ (8)

We note that the size of the $(n+1)$-dimensional universe is determined by the radial distance, $a$, from the center of the black hole.

The extrinsic curvature, $\mathcal{K}_{ij}$, of the brane can be straightforwardly calculated and expressed in term of the functions $a(\tau)$ and $t(\tau)$. One then finds that the equation of motion (2) translates into

$$\frac{dt}{d\tau} = \frac{\kappa a}{h(a)}.$$ (9)
Figure 1: Penrose diagram of an $AdS_{n+2}$-Schwarzschild black hole with the trajectory of the brane. The brane originates in the past singularity, expands to a certain size and subsequently falls into the future singularity as it re-collapses. The dots indicate the moments when the brane crosses the black hole horizon.

In the following we will tune the $(n+1)$-dimensional cosmological constant to zero by setting $\kappa = 1/L$. Combining (9) with (7) leads to an equation that looks suspiciously like the Friedmann equation for a radiation dominated universe,

$$H^2 = \frac{1}{a^2} + \frac{\omega_{n+1} M}{a^{n+1}}.$$  \hfill (10)

In this equation, $H \equiv \dot{a}/a$ is the Hubble ‘constant’ and the dot denotes differentiation with respect to the cosmological time $\tau$. For future purpose, we also give the equation for the time derivative of $H$,

$$\dot{H} = \frac{1}{a^2} - \frac{(n + 1) \omega_{n+1} M}{2 a^{n+1}},$$  \hfill (11)

which is simply obtained by differentiating (10).

3. CFT on the brane

We now want to identify the equation of motion (10) with the $(n+1)$-dimensional Friedmann equation. In particular, we will argue that the radiation can be identified with the finite temperature CFT that is dual to the $AdS$-geometry. To do so, we interpret the last term on the r.h.s. as the contribution of the energy density $\rho$ of the CFT times the $(n+1)$-dimensional Newton constant $G_N$. In the brane-world scenario the relation between the Newton constant $G_N$ in the bulk and the Newton constant $G_N$ on the brane is given by

$$G_N = \frac{G_N L}{(n - 1)}.$$  \hfill (12)
One possible way to derive this fact is to add a small amount of stress energy on the brane and determine how it effects the equation of motion. This same relation is, as we will discuss, also consistent with the identification of the radiation with the dual CFT.

In [14] it was argued that the energy, entropy and temperature of a CFT at high temperatures can be identified with the mass, entropy and Hawking temperature of the AdS black hole [15]. The CFT lives on a space-time which, after Euclidean continuation, has the topology of $S^1 \times S^n$ and whose geometry is identified with the asymptotic boundary of the Euclidean AdS-black hole. We remind the reader that the standard GKPW prescription [12,13] of the AdS/CFT correspondence [16] only fixes the conformal class of the CFT metric. It thus specifies only the ratio of the radius of the $n$-sphere to the Hawking temperature but does not fix the overall scale of the boundary metric. One is therefore free to re-scale the metric as one wishes. It is important to note, however, that such a rescaling does also affect the energy and temperature of the CFT.

To make this more precise, let us consider the asymptotic form of the AdS-Schwarzschild metric. We have

$$\lim_{a \to \infty} \left[ \frac{L^2}{a^2} dS^2_{n+2} \right] = -dt^2 + L^2 d\Omega_n^2,$$

from which we see that the CFT time is equal to the AdS time $t$ only when the radius of the spatial sphere is set equal to $L$. Therefore, if we want the sphere to have a radius equal to say $a$, the CFT time will be equal to $at/L$. The same factor $a/L$ then appears in the relation between the energy $E$ and the black hole mass $M$. One thus finds that the energy for a CFT on a sphere with radius $a$, of volume

$$V = a^n \text{Vol}(S^n),$$

is given by

$$E = M \frac{L}{a}.$$

(14)

Note that the total energy $E$ is not constant during the cosmological expansion, but decreases like $a^{-1}$. This is consistent with the fact that for a CFT the energy density,

$$\rho = \frac{E}{V},$$

scales like $a^{-(n+1)}$. Inserting the relation (14) combined with (12) into the equation of motion (10) leads to

$$H^2 = -\frac{1}{a^2} + \frac{16\pi G_N}{n(n-1)} \rho.$$

(15)

This is the standard Friedmann equation with the appropriate normalization for both terms. By differentiating once with respect to $\tau$ and using the fact that $\dot{\rho} = nH(\rho + p)$, one derives the second FRW equation,

$$\dot{H} = \frac{1}{a^2} - \frac{8\pi G_N}{(n-1)} (\rho + p),$$

(16)
which is equivalent to (11). An observer on the brane, who knows nothing about the AdS-bulk gravity, just notices the normal cosmological expansion. The brane description contains more information, since it also knows about the size of the AdS-black hole.

The movement of the brane in the AdS-black hole background is depicted in the Penrose diagram in figure II. The diagram represents the full geodesically complete black hole geometry including the asymptotic region \( a \to \infty \). If one wants to take the brane as the real boundary, one has to cut away the part to the right of the brane. We see that the brane indeed starts inside the black hole at the past singularity and then, as it expands, it moves away from \( a = 0 \). At late times it does the opposite. The points where the brane crosses the black hole horizon will play a central role in the following discussion and have been marked in the figure. These moments are clearly distinguished from the AdS-perspective, even though nothing special happens to the induced geometry on the brane. So what do these moments mean for an observer on the brane?

4. Entropy and temperature at the horizon

Let us now consider the points at which the brane crosses the horizon. The horizon of the AdS-black hole is located at radius \( a = a_H \), where \( a_H \) is the largest solution to the equation \( h(a) = 0 \), i.e.

\[
\frac{a_H^2}{L^2} + 1 - \frac{\omega_{n+1} M}{a_H^{n-1}} = 0.
\]

(17)

From this equation and the equation of motion (10), one immediately concludes that the Hubble constant at the horizon obeys

\[
H^2 = \frac{1}{L^2},
\]

and hence \( H = \pm 1/L \) depending on whether the brane is expanding or contracting.

Next, let us consider the entropy density. According to [14], the entropy of the CFT is equal to the Bekenstein-Hawking entropy of the AdS-black hole, which is given by the area of the horizon measured in bulk planckian units. The total entropy may thus be expressed as

\[
S = \frac{V_H}{4G_N},
\]

(18)

where \( V_H \) is the area of the horizon,

\[
V_H \equiv a_H^n \text{Vol}(S^n).
\]

Note that the area of an \( n \)-sphere in AdS equals the volume of the corresponding spatial section for an observer on the brane. The total entropy \( S \) is constant during the cosmological evolution but the entropy density,

\[
s = \frac{S}{V},
\]
of course varies with time. It equals
\[ s = (n - 1) \frac{a^n_H}{4G_N L a^n} , \]
where we made use of the relation (12). What makes the moments that the brane crosses the horizon special is that the entropy density is given by a simple multiple of the Hubble constant \( H \). At the horizon \( V = V_H \) and hence the entropy density on the brane is \( s = 1/4G_N \). Now, using the relation (12) and the fact that \( H = 1/L \) one finds that the entropy density equals
\[ s = (n - 1) \frac{H}{4G_N} \quad \text{at} \quad a = a_H . \]
The significance of this relation will be further discussed below.

Also the temperature turns out to have a special value at the horizon. The Hawking temperature measured by an observer who uses \( t \) as his time coordinate is
\[ T_H = \frac{h'(a_H)}{4\pi} , \]
where the prime denotes differentiation with respect to \( a \). Since the CFT time differs from \( t \) by a factor \( a/L \) the CFT-temperature \( T \) will differ from the Hawking temperature \( T_H \) by the same \( a \)-dependent factor,
\[ T = T_H \frac{L}{a} . \]
Using the explicit form of \( h'(a_H) \) and using the fact that \( h(a_H) = 0 \), we eventually find
\[ T = \frac{1}{4\pi a} \left( (n + 1) \frac{a_H}{L} + (n - 1) \frac{L}{a_H} \right) . \]
Now, from the derivation of the brane equation of motion, it follows that the quantities \( H^2 \) and \( -h(a)/a^2 \) only differ by a constant and therefore, at the horizon where \( h(a_H) = 0 \), we have that \( \dot{H} = -h'(a_H)/2a_H \). This can be used to show that the temperature at the horizon may be expressed in the Hubble constant \( H \) and its time derivative \( \dot{H} \) as
\[ T = \frac{-\dot{H}}{2\pi H} , \quad \text{at} \quad a = a_H . \]
5. Entropy formulas and FRW equations

The above relations between the entropy density and temperature on the one hand, and the Hubble constant, its time derivative and Newton’s constant on the other are valid only when the brane crosses the horizon. However, since the entropy density, temperature and energy density all vary in a precisely prescribed manner as a function of the radius \(a\), these relations imply a set of entropy formulas that remain valid at all times.

Before making this point clear, let us first briefly discuss some basic thermodynamics. The first law of thermodynamics,

\[ TdS = dE + pdV, \]

can after some straightforward manipulations be rewritten in terms of the entropy and energy densities \(s\) and \(\rho\) as

\[ Tds = d\rho + n(\rho + p - Ts)\frac{da}{a}, \]

where we used \(dV = nV\frac{da}{a}\). The combination \((\rho + p - Ts)\) is in most standard textbooks on cosmology \([17, 18]\) assumed to vanish, which is equivalent to saying that the entropy and energy are purely extensive. But let us now compute it for the CFT. The energy density is given by

\[ \rho = \frac{ML}{a^{n+1}\text{Vol}(S^n)} a^n. \]

For our purpose, it is convenient to rewrite \(\rho\) in terms of the horizon radius \(a_H\) using \(h(a_H) = 0\). This gives

\[ \rho = \frac{na_H^n}{16\pi G_N a^{n+1}} \left( \frac{L}{a_H} + a_H \right). \]

The pressure follows from \(\rho\) through the equation of state \(p = \rho/n\). Combined with \([13]\) and \((23)\), one gets

\[ \frac{n}{2}(\rho + p - Ts) = \frac{\gamma}{a^2}, \]

where the quantity \(\gamma\) is given by

\[ \gamma = \frac{n(n-1)a_H^{n-1}}{16\pi G_N a^{n-1}}. \]

Equation \((28)\) may be regarded as the definition of \(\gamma\). Physically one can think of \(\gamma\) as describing the response of the energy density under variations of the radius \(a\) or, more precisely, the spatial curvature \(1/a^2\). It thus represents the geometrical Casimir part of the energy density.

We are now ready to present the main entropy formula for CFT’s with an AdS dual. In \([4]\) an entropy formula was already derived and expressed in terms of the total energy and entropy. Here we will give the local version in terms of densities. From the given expressions for the entropy density \(s\), energy density \(\rho\) and \(\gamma\), one finds that \(s\) may be expressed as

\[ s^2 = \left(\frac{4\pi}{n} \right)^2 \gamma \left( \rho - \frac{\gamma}{a^2} \right). \]
As noted in [1], this formula resembles the Cardy formula of a (1+1)-dimensional CFT but is valid for all spatial dimensions $n$.

The formulas (28) and (30) are valid at all times. It will be interesting, however, to study these formulas at the special time when the brane crosses the horizon. First we note that at that time the Casimir quantity $\gamma$ equals

$$\gamma = \frac{n(n-1)}{16\pi G_N}, \quad \text{at } a = a_H. \tag{31}$$

Let us now consider the entropy formula (30). By making the identifications (20) and (31) one sees that this formula exactly reproduces the Friedmann equation! Similarly, one finds that equation (28) reduces to the second FRW equation for $\dot{H}$ by making the same substitutions for $s$ and $\gamma$ and replacing the temperature $T$ by the r.h.s. of (24). In fact, the equations (28) and (30) are equations of state of the CFT and in principle have an interpretation that is independent of gravity or cosmology. It seems therefore rather surprising that the Friedmann equation knows about the thermodynamic properties of the CFT.

### 6. Euclidean brane cosmology

In principle one can use the present setup to calculate the correlation functions of operators in the CFT/FRW cosmology, in particular the stress energy tensor, using the same methods as in the standard $AdS$/CFT setup. This would for example give information about fluctuations in the energy density in the early universe. As described above, the brane starts out as a point in the past singularity of the black hole. The presence of this singularity may lead to problems in performing these calculations in Minkowski signature. On the gravity side a singularity is associated with the UV properties of the theory, i.e. to very high energies. However, through the UV/IR-connection [19] known from $AdS$/CFT, on the field theory side this in fact corresponds to the IR, i.e. to very low energies. As it is the CFT that describes the matter in the universe, this seems strange since conventionally one associates the UV with the early universe.

To calculate correlation functions one can circumvent this problem by analytically continuing to the Euclidean setup. So let us briefly discuss how to describe the Euclidean FRW universe as a brane in an Euclidean $AdS$-Schwarzschild background. Going through the calculation in a similar way as performed above, one arrives at the following Friedmann equation

$$H_E^2 = \frac{1}{a^2} - \frac{16\pi G_N}{n(n-1)} \rho. \tag{32}$$

From this one easily deduces that the universe, when regarded in Euclidean time, undergoes a reverse evolution, starting out very big, collapsing to a minimal size and subsequently re-expanding. This is depicted in figure 4. From the CFT point of view, this means that the universe starts in the far UV, then cools down to a certain minimum temperature after which it re-heats. Note that in this case, the brane does not cross the horizon at all.
Brane worldline

Figure 2: Diagram of Euclidean $AdS_{n+2}$-Schwarzschild with the trajectory of the brane. The horizon is represented by the dot in the middle of the diagram; only the region $a \geq a_H$ is drawn. The brane originates at spatial infinity, collapses to a certain minimal size and subsequently re-expands. It remains outside of the black hole horizon during the entire evolution.

7. Conclusion

In [1] it was argued that the discovered relation between the FRW equations and the entropy formulas sheds light on the meaning of the holographic principle in a cosmological setting [20]. Indeed, it was suggested that the values for $s$ and $T$ on the horizon should be regarded as bounds on these respective quantities. Although we still have no proof of this fact, we would like to present some further arguments in favor of this. At the moment when the brane crosses the horizon, the quantity $\gamma$ is essentially equal to the inverse Newton constant. This means that the response of the energy density to a variation of the curvature is comparable to that of the Einstein action itself. Namely, from (28) and (31) one finds

$$a \left( \frac{\partial \rho}{\partial a} \right)_s = -\frac{n(n-1)}{8\pi G_N a^2}, \quad \text{at } a = a_H.$$ (33)

The right hand side also gives the contribution of the spatial curvature in the equation of motion. Clearly, when this is the case one should reconsider the validity of the usual formulation of gravity, since quantum effects (the Casimir energy density) are of the same order as the spatial curvature. This suggests that a classical description of the geometry of the universe may no longer be well defined and one has to go over to a different, more fundamental formulation of the theory. We have indeed noticed that, at the transition points, the laws that govern the gravitational evolution and the entropy and energy expressions for the CFT, that describes the radiation, merge in a surprising way. This indicates that both sets of equations have a common origin in a single underlying fundamental theory.
