Pregnancy outcomes, Socioeconomic status, Maternal education level, Participant and partner’s income, Maternal occupation
Abstract

Background: Findings of socioeconomic status (SES) effects on adverse pregnancy outcomes varies depending on pregnancy complications, SES indicators, countries, regions, and races. Our aim was to compare three SES indicators (maternal educational level, participant and partner’s income and maternal occupation) and to investigate the relationship with adverse pregnancy outcomes in Chongqing, Southwest China.

Methods: Between 2015 and 2017, we analyzed data from 1273 women in Chongqing, China, enrolled in the Complex Lipids in Mothers and Babies (CLIMB) trial in which mothers received complex lipid supplementation during pregnancy. Information on SES (maternal educational level, participant and partner’s income and maternal occupation) was collected during face-to-face interviews using standard questionnaires. Pregnancy outcomes considered were gestational diabetes mellitus (GDM), premature rupture of membrane (PROM), cesarean section (C-section), preterm birth (PTB), macrosomia, low birth weight (LBW), large for gestational age (LGA), and small for gestational age (SGA). Logistic regression models were used to estimate odds ratios (ORs) and 95% confidence intervals (CIs) for pregnancy outcomes in relation to SES. Supplementation had no effect on pregnancy outcomes, so our analysis did not subdivide our participants on this basis.

Results: Women who were managers or professionals were less likely to suffer from macrosomia and LGA. After adjustment for potential confounders, the ORs for macrosomia and LGA were 0.44 (95% CI: 0.21, 0.95) and 0.48 (95% CI: 0.26, 0.89), respectively. Other pregnancy outcomes were not affected by maternal occupation. Moreover, no significant relationships were observed between the other two SES indicators (participant and partner’s income and maternal education) and adverse pregnancy outcomes.

Conclusions: Our findings suggested that maternal occupation was a more reliable predictor of pregnancy outcomes than maternal education and participant and partner’s income.

Background

Pregnancy outcomes, including gestational diabetes mellitus (GDM), premature rupture of membrane (PROM), cesarean section (C-section), preterm birth (PTB), macrosomia, low birth weight (LBW), large...
for gestational age (LGA), and small for gestational age (SGA), have serious health consequences across the life course for both mothers and their offspring. Adverse pregnancy outcomes are determined by a complex interplay of genetic and environmental factors. One potential environmental parameter is socioeconomic status (SES), also termed as socioeconomic position (SEP) or social class, which refers to the social and economic factors that reflect the positions and prestige individuals or groups hold within the structure of a society [1].

There is a growing literature that explores the influence of SES factors on pregnancy outcomes. Some studies have shown that low SES in pregnant women can increase the risk of adverse pregnancy outcomes such as GDM, PTB, LBW and SGA [2–7]. However, others have suggested that SES indicators have little influence on pregnancy outcomes [7–11]. These contradictory findings show that SES effects on pregnancy outcomes varied depending on pregnancy complications, countries, regions, races, especially on the SES indicators being examined. Scientific studies carried out on the subject can be divided into three different ways of measuring SES: the individual-level (education, income, and occupation), community-level (family background, place of residence and neighborhood), and multilevel or mixed level [12]. Most researchers have used a single SES indicator to reflect an individual’s SES or used some SES indicators as proxies for others [13]. For example, pregnant women with lower education were more likely to suffer from GDM, PTB, LBW and SGA than those with higher education [4, 5, 7], whereas SES (education, occupation, and income) didn’t influence the pregnancy outcomes for North African immigrants [11]. Others have investigated SES by using the community relevance information such as the household and context where a person resides [12, 13]. Campbell et al. [10] found that SES had little impact on adverse birth outcomes by using neighborhood-level socioeconomic variables to present it. There are also those who have used multilevel or mixed level SES. Two cohort studies using principal component analysis based both on individual- and community-indicators to calculate SES found that low SES experienced greater rates of LBW babies than did mothers of high SES but found inconsistent association between SES and macrosomia [14, 15]. However, in practice, the measures used tend to be driven by what is available or has been previously collected. Even when a researcher cannot influence the particular SES measure(s) available in a
study, an understanding of their theoretical basis is important to making appropriate inferences [1]. China has witnessed a remarkable and rapid social-economic growth in the last few decades; investments in education and healthcare have increased accordingly [16, 17], but economic, education and healthcare development varies greatly by different regions of China. To our best knowledge, there are few, if any, investigations of the association between SES and pregnancy outcomes in Southwest China. Therefore, we examined the associations of three measures of SES maternal educational level, participant and partner’s income, and maternal occupation with pregnancy outcomes in urban areas of Chongqing, the largest of the four direct-controlled municipalities in China.

Methods

Study participants

The study participants (n = 1500) were enrolled during September 2015 to June 2017 into the CLIMB study at the First Affiliated Hospital of Chongqing Medical University or Chongqing Health Centre for Women and Children in China; details of the CLIMB study have been described elsewhere [18]. Women who withdrew from the study (n = 146), whose pregnancies were terminated (n = 29), who miscarried (n = 12), or were lost to follow up (n = 40), were excluded from the analysis. 1273 women were thus included in the final analysis.

Data collection and diagnostic criteria

All participants were interviewed by experienced trained nurses at enrollment. Information on socio-demographic factors (maternal age, ethnicity, marital status, maternal education level, participant and partner’s income and maternal occupation), maternal anthropometry (BMI at enrollment), recreational drug/alcohol use before or during pregnancy, smoking before or during pregnancy and any pertinent gynecological and obstetric (gravidity, delivery, abortion, infertility) history was collected during this process. Maternal gestational week was determined by LMP and <mid-trimester ultrasound information; (if the two estimates differed by over 7 days, gestational age was based on the obstetric ultrasound data)

Three indicators were used to define SES: maternal educational level, participant and partner’s
income, and maternal occupation. In our study, maternal educational level was based on total years of schooling and divided into three groups: low educational level (<12 years), medium educational level (12-17 years), high educational level (>17 years). Participant and partner’s income was combined and stratified into four categories: low income (<7000 yuan/month), middle income (7000-10000 yuan/month), middle-high income (10000-16000 yuan/month), high income (>16000 yuan/month). Maternal occupation was classified according to the International Standard Classification of Occupations standard (ISCO-08), and then divided into three groups: no occupation or student, workers/technicians/clerical/service occupations and managers/professionals.

**Diagnostic criteria for pregnancy outcomes**

Pregnancy outcomes were managed by obstetricians and abstracted from the medical records. Pregnancy outcomes included: gestational diabetes mellitus (GDM), premature rupture of membrane (PROM), cesarean section (C-section), preterm birth (PTB), macrosomia, low birth weight (LBW), large for gestational age (LGA), small for gestational age (SGA). The diagnostic criteria are shown in Table 1.

**Statistical analysis**

Data analysis was performed using SPSS (version 19.0, IBM, USA). A value of $P < 0.05$ was considered significant. Data were described as mean ± SD for continuous variables or as percentage for categorical variables. Logistic regression models were used to examine the associations between SES (maternal educational level, participant and partner’s income and maternal occupation) and risk of pregnancy outcomes. The results are presented as odds ratios (ORs) and 95% confidence intervals (CIs), using low educational level (12 years or less), <7000 yuan/month (low income) or no occupation or student as the reference groups. In the multivariable logistic model I, we adjusted for maternal age (continuous), early pregnancy BMI (continuous), Han nationality (yes or no), primiparity (yes or no), history of abortion (yes or no), gestational age at delivery (continuous), newborn sex (female or male). GDM, PIH, PE, PROM, C-section and PTB was not adjusted for gestational age at delivery and newborn sex. In the multivariable logistic model II, we additionally adjusted for the other SES parameters. We did not adjust for maternal smoking and alcohol use during pregnancy, because only
five women reported smoking or alcohol use during pregnancy among 1273 women included in the analysis. The presence of multicollinearity was adjudged if tolerance values were less than 0.4 and the variance inflation (VIF) was greater than 2.5 using Allison’s criteria [19].

Results
The demographic characteristics, socioeconomic status and prevalence of pregnancy outcomes are shown in Table 2. The mean age of women was 28.7 ± 3.6 years, 98.7% were Han nationality and about 77.5% were primiparous. The mean early pregnancy BMI was 21.5 ± 2.9 kg/m². The mean gestational age at birth was 39.4 ± 1.5 weeks, and the mean birth weight was 3310.7 ± 436.9 g. The majority of women had university degree (79.7%), participant and partner’s income in the middle level (36.8%), and had occupation as workers, technicians, clerks and service (48.6%). Approximately 37.2% of pregnant women had C-Section, 25.5% of women affected by GDM and PROM occurred 24.6% in the study. Supplementation had no effect on pregnancy outcomes, so our analysis did not subdivide our participants on this basis (This paper is under review at Scientific Report).

To examine the association between maternal educational level and risk of pregnancy outcomes, logistic regression models were used (Table 3). Compared with women with low educational level (12 years or less), those with medium educational level (12–17 years) were associated with higher risk of PROM, the ORs of PROM were 1.88 (95% CI: 1.13, 3.13) and 1.73 (95% CI: 1.03, 2.91) for those with medium educational level (12–17 years), in the unadjusted model and model I (adjusted for the mothers’ age, BMI, Han nationality, primiparity, history of abortion), respectively. However, in the model II (further adjusted for the participant and partner’s income and maternal occupation), no significant association were observed between education and PROM. Furthermore, no significant association between maternal educational level and other pregnancy outcomes were observed using any of the univariate and multivariable models.

Table 4 presents the ORs and 95% CIs for pregnancy outcomes in association with participant and partner’s income. Only C-section was found to be associated with middle-high income of pregnant women (10000–16000 yuan/month), as compared with low income of pregnant women (<7000 yuan/month) (OR: 0.72; 95% CI: 0.52, 0.99). The differences remained statistically significant (OR:
0.70; 95% CI: 0.50, 0.97) after adjusting for the mothers’ age, BMI, Han nationality, primiparity, history of abortion, but non-significance once there was further adjustment for the mothers’ education and occupation (OR: 0.75; 95% CI: 0.53, 1.06). There were no significant correlations between maternal and partner’s income and any of the other adverse pregnancy outcomes.

Table 5 shows the association between maternal occupation and pregnancy outcomes. A significantly correlation between occupation and macrosomia and LGA was observed. Women who were managers or professionals had a lower risk of macrosomia and LGA. The adjusted ORs of macrosomia was 0.44 (95% CI: 0.21, 0.95) for women were managers or professionals compared to those who had no occupation or who were students. In addition, the adjusted ORs of LGA was 0.48 (95% CI: 0.26, 0.89) for women who were managers or professionals compared to those who had no occupation or who were students. No significant associations between maternal occupation and the other pregnancy complications were observed.

The results of coefficient statistics for multicollinearity are shown in Additional file 1. The estimation of the tolerance value and VIF in the model was greater than 0.4 and less than 2.5, respectively, which revealed that there was no multicollinearity in the multivariate logistic model.

**Discussion**

This study investigated the association between SES and risks of adverse pregnancy outcomes in Chongqing. Our study highlights the influence of maternal occupation on macrosomia and LGA; women who were managers or professionals had lower risks of macrosomia and LGA after adjustment for potential confounders. No significant relationship were observed between maternal occupation and other pregnancy outcomes. The other two indicators of SES (maternal educational level and participant and partner’s income) did not have effect on pregnancy outcomes after adjustment for confounders. As in previous studies that the associations between SES and pregnancy outcomes depended on which SES parameter was used [7, 14, 20]. A systematic review on socioeconomic disparities in adverse birth outcomes demonstrated that different measures may capture different aspects of relative or absolute socioeconomic advantage, which may vary in their importance for birth outcomes [21]. For instance, education levels reflect obtained knowledge and skills-related assets of
an individual, income captures a person’s material resources and social standing, while occupation is reflection of a person’s place in society related to situations linked to working conditions [1].

Macrosomia and LGA have become frequent clinical challenges in obstetrics and neonatology, and are associated with many maternal and neonatal complications [22, 23]. In our study, the incidence of macrosomia and LGA were 5.3% and 9.1%, respectively. These rates are low compared to two recent studies reported in China, which found the incidence of macrosomia to be 8.7% of births [24] and of LGA to be 9.9% [25]. The associations between parameters of SES and PTB, LBW and SGA are established [5, 26–28]; in contrast, few studies have explored the influence of SES on macrosomia and LGA, and the results have been inconsistent. A large population-based study from Shaanxi province found no association between SES and the risk of macrosomia, although the rates of macrosomia were higher in pregnancies associated with high SES [14]. However, the Born in Guangzhou Cohort Study reported that higher family SES was associated with greater risk of macrosomia, independent of potential confounders [15]. Interestingly, our findings were of decreased risk of macrosomia and LGA in pregnancies of women in professional or managerial occupations (parameters of high SES). One reason for the inconsistency may be the different parameters of SES used in previous studies: the Shaanxi cohort study used the Demographic and Health Survey household wealth index to measure SES [14]; the Born in Guangzhou Cohort Study used a principal component analysis based on ten socioeconomic indicators to calculate family SES [15], making it difficult to compare these studies.

Many researchers have used some SES indicators as proxies for others. In our study, the correlations between each indicator of SES showed no multicollinearity, suggesting that the level of maternal educational level or maternal occupation may not be proportionate to participant and partner’s income. This is consistent with the suggestion from other studies that the SES indicators of education level, occupation and income may not be interchangeable [12, 13, 20]. Our results showed that the effect of maternal education on PROM was only apparent at univariate and initial adjustment level. We did not found a statistically significant association between after further adjustment for income and occupation. A similar finding pertained when we examined the associations between C-section
and parameters of SES; no significant association was found after adjustment for all cofounders. This finding indicated that education and income may less important as independent factors than other risks related to pregnancy outcomes, and is in accord with other studies [10, 29–31]. Although most health studies that consider SES treat socioeconomic characteristics as potential confounders of relationships between other variables and health, others explicitly examine relationships between SES and health, to better understand the associations [13]. Despite such endeavours, the effect of SES on pregnancy outcomes has yet to be adequately explained.

This study had several limitations. Firstly, this study was conducted in the First Affiliated Hospital of Chongqing Medical University and the Chongqing Health Center for Women and Children which were located in the main urban area of Chongqing, thus limiting generalizability of our results to rural populations. Secondly, information on socio-demographic factors was obtained using face to face questionnaires, which might have introduced biases or errors. In China, income is considered private for individuals, thus participant and partner’s income may have been underreported. Maternal occupation was obtained at enrollment, it may have changed during the pregnancy. Finally, SES is a complex and multidimensional concept comprising a range of factors encompassing education, occupation, income, family background, home ownership, car ownership and place of residence and neighborhood. We lacked such comprehensive data for our study population and so our analysis was based on the three generic indicators of SES: education, income and occupation.

Conclusions
Our results showed that only maternal occupation was observed to be independently associated with macrosomia and LGA after full adjustment for potential confounders. In contrast, education and income were not associated with adverse pregnancy outcomes. Future studies should consider validating our findings using more comprehensive measures, to understand the mechanisms underlying the link between SES and adverse pregnancy outcomes, and why maternal occupation may play a more important role than education and income.

Declarations

Ethics approval and consent to participate

Written informed consent was obtained from all participants at enrollment. Ethical approval for this study was provided by the Ethics Committee of Chongqing Medical University (2014034). The study was conducted in accordance with the principles in the Declaration of Helsinki 1964 and the International Conference on Harmonisation Good Clinical Practice E6 (ICH-GCP). This trial was prospectively registered with the Chinese Clinical Trial Register (ChiCTR-IOR–16007700).

Consent for publication

Not applicable.

Availability of data and materials

The datasets used and/or analysed during the current study are available from the corresponding author on reasonable request.

Competing interests

The authors declare that they have no competing interests.

Funding

This study was supported by the New Zealand Primary Growth Partnership post farm gate dairy programme, funded by Fonterra Co-operative Group Ltd, New Zealand and the New Zealand Ministry for Primary Industries. The funding bodies played no role in designing the study; in collecting, analyzing, or interpreting data; or in writing the manuscript.

Authors’ contributions

YYX, WZ, TLH, CC, HZ, HBQ and PB conceived and designed research; TZ and YTC recruited the patients. TZ, QT, QT, TK and RYZ performed data checking, cleaning and the statistical analysis. ZT wrote the draft of manuscript text and prepared the tables. YYX, WZ, TLH, CC, HZ, HBQ and PB revised the manuscript. All authors read and approved the final version of the article.
Acknowledgements

We would like to thank the women who participated in this study and the health-care staff who were involved in data collection at the First Affiliated Hospital of Chongqing Medical University and the Chongqing Health Center for Women and Children.

Tables

Table 1. Diagnostic criteria of pregnancy outcomes

| Pregnancy outcomes | Diagnostic criteria |
|--------------------|---------------------|
| GDM                | A 75g oral glucose tolerance (OGTT) at 24-28 weeks, fasting, 1 and 2 h plasma glucose ≥ 5.1, ≥ 10.0, ≥ 8.5 mmol/L, respectively |
| PROM               | Rupture of membranes before the onset of labor |
| PTB                | Delivery before 37 weeks |
| Macrosomia         | Birth weight ≥ 4000g |
| LBW                | Birth weight < 2500g |
| LGA                | Birth weight > 90th percentile of weight for a specific gestational age |
| SGA                | Birth weight < 10th percentile of weight for a specific gestational age |

Abbreviation: GDM gestational diabetes mellitus, PIH pregnancy-induced hypertension, PE pre-eclampsia, PROM premature rupture of membrane, PTB preterm birth, LBW low birth weight, LGA large for gestational age, SGA small for gestational age

Table 2. Characteristics of the study participants and their newborns and frequency of pregnancy outcomes
### Characteristic

**Maternal characteristics**

| Characteristic                                      | Value                  |
|-----------------------------------------------------|------------------------|
| Maternal age (mean ± sd, years)                     | 28.7 ± 3.6             |
| BMI (mean ± sd, kg/m²)                              | 21.5 ± 2.9             |
| Nationality (% Han)                                 | 98.7                   |
| Marital status (% married)                          | 97.9                   |
| Primiparity (%)                                     | 77.5                   |
| History of abortion (%)                             | 47.3                   |
| Smoking or drinking during pregnancy (%)            | 0.4                    |

**Maternal educational level**

- Low educational level (% 12 years or less) 9.5
- Medium educational level (% 12-17 years) 79.7
- High educational level (% more than 17 years) 10.8

**Participant and partner's income**

- <7000yuan/month (% Low income) 21.3
- 7000-10000yuan/month (% Middle income) 36.8
- 10000-16000yuan/month (%Middle-high income) 30.2
- >16000yuan/month (% High income) 11.7

**Maternal occupation**

- No occupation or student (%) 21.7
- Workers/technicians/clerical/service occupations (%) 48.6
- Managers/professionals (%) 29.7

**Neonatal characteristics**

| Characteristic                                      | Value                  |
|-----------------------------------------------------|------------------------|
| Gestational age at delivery (mean ± sd, week)       | 39.4 ± 1.5             |
| Birthweight (mean ± sd, g)                          | 3310.7 ± 436.9         |
| Birthlength (mean ± sd, cm)                         | 49.7 ± 1.9             |

**Newborn sex (n, %)**

- Male 663 (52.2)
- Female 608 (47.8)

**Pregnancy outcomes**

| Characteristic   | Value                  |
|------------------|------------------------|
| GDM (n, %)       | 325 (25.5)             |
| PROM (n, %)      | 313 (24.6)             |
| C-section (n, %) | 474 (37.2)             |
| PTB (n, %)       | 36 (2.8)               |
| Macrosomia (n, %)| 67 (5.3)               |
| LBW (n, %)       | 32 (2.5)               |
| LGA (n, %)       | 116 (9.1)              |
| SGA (n, %)       | 94 (7.4)               |

Abbreviations: BMI body mass index, GDM gestational diabetes mellitus, PROM premature rupture of
membrane, C-section cesarean section, PTB preterm birth, LBW low birth weight, LGA large for gestational age, SGA small for gestational age

a: Missing 11 data of birthweight
b: Missing 30 data of birthlength
c: Missing 2 data of newborn sex

Table 3. Odds ratios (ORs) and 95% confidence intervals (CI) for associations between maternal educational levels and adverse pregnancy outcomes
| Pregnancy outcomes | Education | No. (%)  | Unadjusted OR (95%CI) | Model I OR (95%CI) | Model II OR (95%CI) |

Values are odds ratios (95% confidence intervals), *p<0.05

Model 1 was adjusted for maternal age, BMI, Han nationality, primiparity, history of abortion, gestational age at delivery, newborn sex; GDM, PROM, C-section and preterm birth was not adjusted for gestational age at delivery, newborn sex

Model 2 was additionally adjusted for participant and partner’s income, maternal occupation; GDM,
PROM, C-section and preterm birth was not adjusted for gestational age at delivery, newborn sex

Abbreviations: OR Odds ratios, CI confidence intervals, GDM gestational diabetes mellitus, PROM premature rupture of membrane, C-section cesarean section, PTB preterm birth, LBW low birth weight, LGA large for gestational age, SGA small for gestational age

Maternal educational level:
Low educational level (12 years or less)
Medium educational level (12-17 years)
High educational level (more than 17 years)

Table 4. Odds ratios (ORs) and 95% confidence intervals (CI) for associations between participant and partner’s income and pregnancy outcomes

Values are odds ratios (95% confidence intervals), *p<0.05

Model 1 was adjusted for maternal age, BMI, Han nationality, primiparity, history of abortion, gestational age at delivery, newborn sex; GDM, PROM, C-section and preterm birth was not adjusted for gestational age at delivery, newborn sex

Model 2 was additionally adjusted for maternal educational level, participant and partner’s income; GDM, PROM, C-section and preterm birth was not adjusted for gestational age at delivery, newborn sex
sex

Abbreviations: OR Odds ratios, CI confidence intervals, GDM gestational diabetes mellitus, PROM premature rupture of membrane, C-section cesarean section, PTB preterm birth, LBW low birth weight, LGA large for gestational age, SGA small for gestational age

Maternal occupation

No occupation or student
Workers/technicians/clerical/service occupations
Managers/professional
