April 7, 2015

Abstract

In this paper, we consider the initial and boundary value problem of a simplified nematic liquid crystal flow in dimension three and construct two examples of finite time singularity. The first example is constructed within the class of axisymmetric solutions, while the second example is constructed for any generic initial data (u₀, d₀) that has sufficiently small energy, and d₀ has a nontrivial topology.

1 Introduction

Let Ω ⊂ R^n (n = 2, 3) be a bounded, smooth domain, and 0 < T ≤ +∞. In this paper, we will consider a simplified version of the hydrodynamic flow of nematic liquid crystals on Ω × (0, T) given by

\[
\begin{aligned}
&\begin{cases}
  u_t + u \cdot \nabla u - \mu \Delta u + \nabla P = -\lambda \nabla \cdot \left( \nabla d \odot \nabla d - \frac{1}{2} |\nabla d|^2 I_n \right), \\
  \nabla \cdot u = 0, \\
  d_t + u \cdot \nabla d = \gamma \left( \Delta d + |\nabla d|^2 d \right),
\end{cases}
\end{aligned}
\]

(1.1)

where u(x, t) : Ω × (0, T) → R^n is the velocity field of the underlying incompressible fluid, d(x, t) : Ω × (0, T) → Σ² := \{ v ∈ R³ : |v| = 1 \} represents the (averaged) orientation field of nematic liquid crystal molecules, P(x, t) : Ω × (0, T) → R is the pressure function, x ∈ Ω, \nabla \cdot denotes the divergence operator on R^n, \nabla d \odot \nabla d = (\langle \partial d / \partial x_i, \partial d / \partial x_j \rangle)_{1 \leq i,j \leq n} ∈ R^{n×n} represents the stress tensor induced by the orientation field d, and I_n = (δ_{ij})_{1 \leq i,j \leq n} ∈ R^{n×n} is the identity matrix of order n. The parameters μ, λ and γ are positive constants representing the fluid viscosity, the competition between kinetic energy and potential energy, and the macroscopic elastic relaxation time for the molecular orientation field respectively.

The system (1.1), first proposed by Lin [25], is a simplified version of the general Ericksen-Leslie system modeling the hydrodynamic flow of nematic liquid crystal materials proposed by Ericksen [10] and Leslie [24] during the period between 1958 and 1968. The system (1.1) is a macroscopic continuum description of the time evolution of the material under the influence of both the fluid velocity field and the macroscopic description of the microscopic orientation configurations of rod-like liquid crystals. The interested readers can refer to [10], [24], [25], and Lin-Liu [27] for more details.

The system (1.1) is a strongly coupling system between the incompressible Naiver-Stokes equation and the heat flow of harmonic maps into S², and relates to several important equations:

1. When $\lambda \equiv 0$ or $d \equiv e_0 \in S^2$, the system (1.1)$_{1,2}$ reduces to the incompressible Navier-Stokes equation (or NSE) that has been extensively studied for decays (see Lions [35], Temam [39]). Although the existence of global weak solutions to the initial value problem to NSE has been established by Leray [23] in 1930’s and Hopf [20] in 1950’s, it is a long outstanding open problem whether NSE admits a global smooth solution for a smooth initial data in dimension $n = 3$. It is also an open problem whether Leray-Hopf weak solutions to NSE are unique in dimension $n = 3$.

2. When $u \equiv 0$ and $\gamma = 1$, the equation (1.1)$_3$ reduces to the heat flow of harmonic maps into $S^2$. For dimension $n = 2$, the existence of a unique global weak solution, which has at most finitely many singular points, has been proved by Struwe [38] and Chang [1]. In higher dimensions, the existence of a global, partially regular weak solution has also been obtained by Chen-Struwe [4] and Chen-Lin [5]. Examples of finite time singularities have been constructed by Coron-Ghidaglia [7] and Chen-Ding [6] for $n \geq 3$. In an important work [3], Chang-Ding-Ye constructed examples of finite time singularities when $n = 2$ (see Grotowski [13, 14] for some generalizations to $n \geq 3$) by studying the equation

$$\varphi_t = \varphi_{rr} + \frac{\varphi_r}{r} - \frac{\sin(2\varphi)}{2r^2}, \quad (r, t) \in (0, 1) \times (0, +\infty).$$

(1.2)

The interested readers can refer to Lin-Wang [31] and references therein for more details.

3. Another important case we want to mention is $\gamma \equiv 0$. The system (1.1) for $(u, d)$ is closely related to the MHD system for $(u, \psi)$ provided we identify $\psi = \nabla \times d$. There have been many interesting works on global small solutions to the MHD system recently. See, for example, Lin-Zhang [32] and Lin-Zhang [33] for $n = 3$ and Lin-Zhang-Xu [34] for $n = 2$.

The system (1.1) has attracted a lot of interests and generated many interesting research works recently. Here we would like to mention a few of previous results. In dimensions two, Lin-Lin-Wang [26] have proved the existence of global Leray-Hopf type weak solutions to (1.1) with initial and boundary conditions, which is smooth away from finitely many possible singular times (see Hong [17] for (1.1) in $\Omega = \mathbb{R}^2$, Hong-Xin [18] and Xu-Zhang [41] for other related works). Lin-Wang [29] have also proved the uniqueness for such weak solutions. It remains a very challenging open problem to establish the existence of global Leray-Hopf type weak solutions and partial regularity of suitable weak solutions to (1.1) in dimension three. Very recently, Lin-Wang [28] have proved the existence of global weak solutions in dimension three under the assumption that $d_0(x) \in S^2_+$ for a.e. $x \in \Omega$ by developing some new compactness arguments, here $S^2_+$ is the upper hemisphere. When $\Omega \equiv \mathbb{R}^3$, the local well-posedness of (1.1) was obtained for initial data $(u_0, d_0)$, where $(u_0, \nabla d_0) \in L^3_{uloc}(\mathbb{R}^3)$, the space of uniformly locally $L^3$-integrable functions, has small norms, by Hineman-Wang [16]. While the global well-posedness of (1.1) was obtained by Wang [40] for $(u_0, d_0) \in \text{BMO}^{-1} \times \text{BMO}$ with small norms. A BKM type blow-up criterion was obtained for local strong solutions to (1.1) by Huang-Wang [21] (see also Hong-Li-Xin [19]). More references can be found in the survey paper by Lin-Wang [30].

It is a very interesting question whether the short time smooth solutions to the nematic liquid crystal flow (1.1) develop singularities in finite time. It is not hard to verify that in dimension two, if $d$ is the heat flow of harmonic maps with finite time singularity, constructed by [3], and if we set $u \equiv 0$, then $(u, d)$ is also a solution of (1.1) which has a finite time singularity. However, it will be more desirable to construct an example in which the fluid velocity field $u$ is non-trivial. In this paper, building upon the construction by [3] on the heat flow of harmonic maps, we are able to construct in dimension three the first example of solutions to (1.1) with finite time singularity in
which both the fluid field $u$ and the director field $d$ are non-trivial. More precisely, we consider (1.1) in the class of axisymmetric solutions without swirls and show that for a suitably chosen domain $\Omega$ and initial-boundary data $(u_0, d_0)$, the short time smooth solution $(u, d)$ to (1.1) develops a finite time singularity.

Let $B_1^2 \subset \mathbb{R}^n$ denote the unit ball centered at 0. Now we state our first result.

**Theorem 1.1** Let $\Omega = B_1^2 \times [0, 1]$. There exists $\varphi_0 \in C^\infty([0, 1])$, with $\varphi_0(0) = 0$ and $|\varphi_0(1)| > \pi$, such that if

$$u_0(x) = (x, y, -2z),$$

and

$$d_0(x) = \left( \frac{x}{\sqrt{x^2 + y^2}} \sin \varphi_0\left(\sqrt{x^2 + y^2}\right), \frac{y}{\sqrt{x^2 + y^2}} \sin \varphi_0\left(\sqrt{x^2 + y^2}\right), \cos \varphi_0\left(\sqrt{x^2 + y^2}\right) \right),$$

for $x = (x, y, z) \in \Omega$, then the short time smooth solution $(u, d, P)$ to the system (1.1) in $\Omega$, under the initial and boundary condition:

$$\begin{cases} u(x, 0) = u_0(x), d(x, 0) = d_0(x), & x \in \Omega, \\ u(x, t) = u_0(x) & x \in \partial \Omega, \ t > 0, \\ d(x, t) = d_0(x) & x \in \partial B_1^2 \times [0, 1], \ t > 0, \\ \frac{\partial d}{\partial n}(x, t) = 0 & x \in B_1^2 \times \{0, 1\}, \ t > 0. \end{cases} \tag{1.3}$$

must blow up at time $T_0$ for some $0 < T_0 = T_0(\varphi_0) < +\infty$.

Since $\Omega$ is axisymmetric and $(u_0, d_0)$ is axisymmetric without swirls, the uniqueness of short time smooth solution $(u, d)$ of (1.1) implies that it is axisymmetric without swirls. By converting the system (1.1) into the form of being axisymmetric without swirls, the proof of Theorem 1.1 utilizes two interesting observations:

1) The velocity $u$ is a static solution to the Navier-Stokes equation. In fact, $u(x, y, z, t) = (x, y, -2z)$ is spatial gradient of the quadratic harmonic polynomial $h(x, y, z) = \frac{1}{2}x^2 + \frac{1}{2}y^2 - z^2$.

2) The angle function $\varphi(r, t)$, associated with the orientation field $d(x, t)$, solves a drifted version of the equation (1.2):

$$\varphi_t + r\varphi_r = \varphi_{rr} + \frac{\varphi_r}{r} - \frac{\sin(2\varphi)}{2r^2}, \ (r, t) \in (0, 1) \times (0, +\infty). \tag{1.5}$$

After a suitable re-parameterization to handle the contribution from the drifting term $r\varphi_r(r, t)$ in (1.5), we can modify the construction of [3] to build a subsolution to (1.5) that blows up at finite time. This, combined with the comparison principle, yields the finite time singularity of (1.5).

In particular, $u$ is smooth in this example. This is consistent with known results of the Navier-Stokes equation: any local axisymmetric solution to the Navier-Stokes equation, without swirls, is globally smooth (see, for example, Leonardi-Málek-Nečas-Pokorný [22]). Therefore, the finite time singularity arises essentially from the orientation field $d$.

Now we would like to make a few comments related to Theorem 1.1
Remark 1.2  

a) By modifying the argument of Chang-Ding \cite{2}, we will show, in Theorem 2.5 below, that (1.5) admits a global smooth solution if the initial-boundary value \( \varphi_0 \in C^\infty([0,1]) \) satisfies \( \varphi_0(0) = 0 \) and \( \| \varphi_0 \|_{C([0,1])} \leq \pi \).

b) It is a natural question to ask whether the stress tensor \( S := \nabla d \otimes \nabla d - \frac{1}{2} |\nabla d|^2 \mathbb{I}_3 \) blows up in finite time, if \((u,d,P)\) is the solution constructed by Theorem 1.1. The calculations in Section 5 seem to suggest that \( S \) may not blow up.

c) Since \((u_0(x) \cdot \nu) \neq 0\) on \( \partial \Omega \), here \( \nu \) denotes the outward unit normal of \( \partial \Omega \), it is unclear whether the solution \((u,d,P)\) constructed by Theorem 1.1 enjoys the energy dissipation inequality for \( 0 \leq t < T_0 \):

\[
\frac{d}{dt} \int_\Omega (|u|^2 + |\nabla d|^2)(t) + 2 \int_0^t \int_\Omega (\mu |\nabla u|^2 + \frac{\lambda}{\gamma} |\Delta d + |\nabla d|^2 d|^2) \leq 0. \tag{1.6}
\]

See Section 5 for more details.

It is the question from Remark 1.2 c) that motivates us to construct another example in which the solution \((u,d,P)\) to (1.1) develops finite time singularity, and satisfies the energy dissipation inequality (1.6).

In order to state it, we need some notations. Denote the north pole by \( e = (0,0,1) \in S^2 \). Set

\[
C_{0,\text{div}}(B_1^3, \mathbb{R}^3) := \left\{ v \in C^\infty(B_1^3, \mathbb{R}^3) \mid \nabla \cdot v = 0 \right\},
\]

and

\[
C_e^\infty(B_1^3, \mathbb{S}^2) := \left\{ d \in C^\infty(B_1^3, \mathbb{S}^2) \mid d = e \text{ on } \partial B_1^3 \right\}.
\]

For continuous maps \( f, g \in C(\overline{B_1^3}, \mathbb{S}^2) \), with \( f = g \) on \( \partial B_1^3 \), we say that \( f \) is homotopic to \( g \) relative to \( \partial B_1^3 \) if there exists a continuous map \( \Phi \in C(\overline{B_1^3} \times [0,1], \mathbb{S}^2) \) such that

(i) \( \Phi(\cdot,t) = f(\cdot) = g(\cdot) \) on \( \partial B_1^3 \), for all \( 0 \leq t \leq 1 \); and

(ii) \( \Phi(\cdot,0) = f(\cdot) \) and \( \Phi(\cdot,1) = g(\cdot) \) in \( B_1^3 \).

Now we have

**Theorem 1.3** There exists \( \epsilon_0 > 0 \) such that if \( u_0 \in C_{0,\text{div}}(B_1^3, \mathbb{R}^3) \) and \( d_0 \in C_e^\infty(B_1^3, \mathbb{S}^2) \) satisfies that \( d_0 \) is not homotopic to the constant map \( e : B_1^3 \to \mathbb{S}^2 \) relative to \( \partial B_1^3 \), and

\[
E(u_0, d_0) := \frac{1}{2} \int_{B_1^3} (|u_0|^2 + |\nabla d_0|^2) \leq \epsilon_0^2. \tag{1.7}
\]

Then the short time smooth solution \((u,d,P) : B_1^3 \times [0,T) \to \mathbb{R}^3 \times \mathbb{S}^2 \) to the nematic liquid crystal flow (1.7), under the initial-boundary condition

\[
\begin{aligned}
(u,d)_{t=0} &= (u_0, d_0), \text{ in } B_1^3, \\
(u,d)_{|\partial B_1^3} &= (0,e), \text{ for } 0 < t < T,
\end{aligned} \tag{1.8}
\]

must blow up before time \( T = 1 \).

The following remark indicates that there are ample examples of \((u_0, d_0) \in C_{0,\text{div}}(B_1^3, \mathbb{R}^3) \times C_e^\infty(B_1^3, \mathbb{S}^2) \) satisfying the conditions of Theorem 1.3.

**Remark 1.4**  

a) Let \( H(z,w) = (|z|^2 - |w|^2, 2zw) : \mathbb{S}^3 \equiv \{(z,w) \in \mathbb{C} \times \mathbb{C} : |z|^2 + |w|^2 = 1\} \to \mathbb{S}^2 \subset \mathbb{R} \times \mathbb{C} \) be the Hopf map. Let \( D_\lambda(x) = \lambda x : \mathbb{R}^3 \to \mathbb{R}^3 \) be the dilation map for \( \lambda > 0 \). Then \( : \mathbb{S}^3 \to \mathbb{R}^3 \).
be the stereographic projection map from \( e \), and \( \Psi_\lambda = \Pi^{-1} \circ D_\lambda \circ \Pi : S^3 \to S^3 \). Then direct calculations imply that the Dirichlet energy of \( H \circ \Psi_\lambda : S^3 \to S^2 \) satisfies

\[
\lim_{\lambda \to \infty} \int_{S^3} |\nabla (H \circ \Psi_\lambda)|^2 \, d\sigma = 0.
\]

Moreover, it is easy to see that \( H \circ \Psi_\lambda \) is not homotopic to the constant map \( e : S^3 \to S^2 \). Let \( \Phi \in C^\infty(B^3_1, S^3) \) such that \( \Phi : B^3_1 \to S^3 \setminus \{e\} \) is a diffeomorphism and \( \Phi = e \) on \( \partial B^3_1 \). Now we can check that for any \( u \in C^\infty_{0, \text{div}}(B^3_1, \mathbb{R}^3) \), since

\[
\lim_{\lambda \to \infty} E(\lambda^{-1} u, H \circ \Psi_\lambda \circ \Phi) = 0,
\]

we can find a sufficiently large \( \lambda_0 > 0 \) depending on \( u \), \( H \), and \( \Phi \) such that

\[
(u_0, d_0) := (\lambda^{-1} u, H \circ \Psi_{\lambda_0} \circ \Phi) : B^3_1 \to \mathbb{R}^3 \times S^2
\]
satisfies the condition (1.7) of Theorem 1.3 and \( d_0 \) is not homotopic to the constant map \( e \) relative to \( \partial B^3_1 \).

b) The initial data \( d_0 \) constructed in a) has previously been used by Ding-Wang [9] in the construction of finite time singularity of the Landau-Lifshitz-Gilbert system modeling the continuum theory of ferromagnetism.

Since precise values of the parameters \( \lambda \) and \( \gamma \) in (1.1) don’t play a role in this paper, for simplicity we assume henceforth that

\[
\lambda = \gamma = 1.
\]

The paper is organized as follows. In Section 2, we will derive the axisymmetric form of (1.1), without swirls. In Section 3, we will sketch the proof of local smooth axisymmetric solutions of (2.2) without swirls. In Section 4, we will prove the existence of global smooth axisymmetric solutions of (2.2) without swirls, when the initial data \( \varphi_0 \) satisfies \( \varphi_0(0) = 0 \) and \( |\varphi_0(r)| \leq \pi \) for all \( 0 \leq r \leq 1 \).

In Section 5, we will present in details the example of solutions to (2.2) with finite time singularity for suitably chosen initial data \( \varphi_0 \in C^\infty([0, 1]) \), with \( \varphi_0(0) = 0 \) and \( |\varphi_0(1)| > \pi \). In Section 6, we will outline the proof of Theorem 1.3.

## 2 Axisymmetric form of (1.1) without swirls

In this section, we will derive the axisymmetric form of (1.1) without swirls. We would like to mention that Dong-Lei [8] have constructed a global smooth axisymmetric solution of (1.1) in dimension two.

Let \( (r, \theta, z) \) denote the cylindrical coordinates of \( \mathbb{R}^3 \), and set

\[
e^r = (\cos \theta, \sin \theta, 0), \quad e^\theta = (-\sin \theta, \cos \theta, 0), \quad e^3 = (0, 0, 1)
\]
as the canonical orthonormal base of \( \mathbb{R}^3 \) in the cylindrical coordinates. For \( \alpha \in [0, 2\pi] \), let \( R_\alpha \in \text{SO}(3) \) denote the rotation map of angle \( \alpha \) with respect to the \( z \)-axis. Recall that a vector field \( v : \mathbb{R}^3 \to \mathbb{R}^3 \) is axisymmetric if

\[
R_\alpha^{-1} \circ v \circ R_\alpha = v, \ \forall \ \alpha \in [0, 2\pi].
\]

Hence any axisymmetric vector field \( v \) can be written as

\[
v(r, \theta, z) = v^r(r, z)e^r + v^\theta(r, z)e^\theta + v^3(r, z)e^3.
\]
If, in addition, \( v^\alpha \equiv 0 \), we say \( v \) is axisymmetric without swirls.

A solution \((u, d, P)\) of the nematic liquid crystal flow equation (1.1) is said to be axisymmetric without swirls, if

\[
\begin{aligned}
    u(r, \theta, z, t) &= u^r(r, z, t)e^r + u^z(r, z, t)e^z, \\
    d(r, \theta, z, t) &= \sin \varphi(r, z, t)e^r + \cos \varphi(r, z, t)e^3, \\
    P(r, \theta, z, t) &= P(r, z, t).
\end{aligned}
\]

A domain \( \Omega \subset \mathbb{R}^3 \) is axisymmetric if it is invariant under a rotation map \( R_\alpha \) for any \( \alpha \in [0, 2\pi] \). Now we have

**Lemma 2.1** For any axisymmetric domain \( \Omega \subset \mathbb{R}^3 \), if \((u, d, P)\) is an axisymmetric without swirl solution of the system (1.1) in \( \Omega \times \mathbb{R}_+ \), then \((u^r, u^z, \varphi, P)\) solves

\[
\begin{aligned}

\begin{cases}
    &\frac{\ddot{D}u^r}{Dt} - \mu \Delta u^r + \frac{\mu}{r^2} u^r + P_r = -\left(\bar{\Delta} \varphi - \frac{\sin(2\varphi)}{2r^2}\right) \varphi_r, \\
    &\frac{\ddot{D}u^z}{Dt} - \mu \Delta u^z + P_z = -\left(\bar{\Delta} \varphi - \frac{\sin(2\varphi)}{2r^2}\right) \varphi_z, \\
    &\frac{1}{r}(ru^r)_r + (u^3)_z = 0, \\
    &\frac{\ddot{D}\varphi}{Dt} - \bar{\Delta} \varphi = -\frac{\sin(2\varphi)}{2r^2},
\end{cases}
\end{aligned}
\]

where

\[
\begin{aligned}
    \bar{D} := \partial_t + u^r \partial_r + u^z \partial_z, \\
    \bar{\Delta} := \partial^2_r + \frac{1}{r} \partial_r + \partial^2_z.
\end{aligned}
\]

**Proof.** Let’s first show (2.2)3. By (1.1)2 and the definition of \( u \), we have

\[
\begin{aligned}
    0 &= \partial_x \left( \frac{u^r x}{r} \right) + \partial_y \left( \frac{u^r y}{r} \right) + \partial_z (u^3) \\
    &= \partial_x (u^r x) + \partial_y (u^r y) - \frac{u^r (x \partial_x r + y \partial_y r)}{r^2} + \partial_z (u^3) \\
    &= \frac{2u^r}{r} + \partial_r u^r + u^3 - \frac{u^r}{r} \left( ru^r \right)_r + u^3_z.
\end{aligned}
\]

For (2.2)4, since \( d \) can be written as

\[
    d = (\cos \theta \sin \varphi, \sin \theta \sin \varphi, \cos \varphi),
\]

direct calculations imply that

\[
\begin{aligned}
    d_r &= (\cos \theta \cos \varphi, \sin \theta \cos \varphi, -\sin \varphi) \varphi_t, \\
    d_r &= (\cos \theta \cos \varphi, \sin \theta \cos \varphi, -\sin \varphi) \varphi_r, \\
    d_\theta &= (-\sin \theta \sin \varphi, \cos \theta \sin \varphi, 0), \\
    d_z &= (\cos \theta \cos \varphi, \sin \theta \cos \varphi, -\sin \varphi) \varphi_z,
\end{aligned}
\]

and

\[
\begin{aligned}
    d_{rr} &= \left( (\cos \varphi \varphi_{rr} - \sin \varphi \varphi_{r}^2)(\cos \theta, \sin \theta), -(\sin \varphi \varphi_{rr} + \cos \varphi \varphi_{r}^2) \right), \\
    d_{\theta \theta} &= (\cos \theta \sin \varphi, -\sin \theta \sin \varphi, 0), \\
    d_{zz} &= \left( (\cos \varphi \varphi_{zz} - \sin \varphi \varphi_{z}^2)(\cos \theta, \sin \theta), -(\sin \varphi \varphi_{zz} + \cos \varphi \varphi_{z}^2) \right).
\end{aligned}
\]
Hence we have
\[ |\nabla d|^2 = \varphi_r^2 + \frac{1}{r^2} \sin^2 \varphi + \varphi_z^2, \]
and
\[ \Delta d + |\nabla d|^2 d = (\varphi_{rr} + \varphi_{zz} + \frac{1}{r} \varphi_r - \frac{\sin(2\varphi)}{2r^2}) (\cos \theta \cos \varphi, \sin \theta \cos \varphi, -\sin \varphi). \]
By the definition of \( u \), we also have
\[ u \cdot \nabla d = (u^r \partial_r + u^3 \partial_z)d = (u^r \varphi_r + u^3 \varphi_z) (\cos \theta \cos \varphi, \sin \theta \cos \varphi, -\sin \varphi). \]
Putting these identities into (1.1), we obtain
\[ \varphi_t + u^r \varphi_r + u^3 \varphi_z = (\varphi_{rr} + \varphi_{zz} + \frac{1}{r} \varphi_r - \frac{\sin(2\varphi)}{2r^2}). \]
This yields the equation (2.2). Now we want to derive the momentum equations (2.2) Since
\[ \Delta e_r = -\frac{1}{r^2} e_r, \]
(2.3) it follows from (1.1) and (2.3) that
\[ \frac{Du^r}{Dt} - \mu \Delta u^r + \frac{mu^3}{r^2}u^r + P_r) e^r + (\frac{Du^3}{Dt} - \mu \Delta u^3 + P_z) e^3 = -\Delta d \cdot \nabla d. \]
From (2.3), we also have
\[ \Delta d = (\Delta - \frac{1}{r^2})(\sin \varphi)e^r + \Delta (\cos \varphi)e^3. \]
Since
\[ \nabla d = \nabla (\sin \varphi)e^r + \nabla (\cos \varphi)e^3 + \sin \varphi \nabla e^r, \]
and
\[ \langle \nabla e^r, e^r \rangle = \langle \nabla e^r, e^3 \rangle = 0, \]
we have
\[ -\Delta d \cdot \nabla d = - (\Delta - \frac{1}{r^2})(\sin \varphi) \nabla (\sin \varphi) - \Delta (\cos \varphi) \nabla (\cos \varphi) \]
\[ = (\Delta (\cos \varphi) \sin \varphi - (\Delta - \frac{1}{r^2})(\sin \varphi) \cos \varphi) (\varphi_r e^r + \varphi_z e^3) \]
\[ = - (\varphi_{rr} + \varphi_{zz} + \frac{1}{r} \varphi_r - \frac{\sin(2\varphi)}{2r^2}) (\varphi_r e^r + \varphi_z e^3). \]
Putting (2.5) into (2.4) yields (1.1)\textsuperscript{1,2}.\]

In order to construct a solution of (2.2) with finite time singularity, we further consider the domain to be the round cylinder \( \Omega = B^2 \times [0,1] \) and an axisymmetric, without swirl, solution \( (u, P, d) \) in the special form:
\[
\begin{cases}
  u(r, \theta, z, t) := v(r, t)e^r + w(z, t)e^3, \\
  d(r, \theta, z, t) := \sin \varphi(r, t)e^r + \cos \varphi(r, t)e^3, \\
  P(r, \theta, z, t) := Q(r, t) + R(z, t).
\end{cases}
\]
Then (2.2) becomes
\[
\begin{aligned}
   v_t + v v_r - \mu(v_{rr} + \frac{v_r}{r^2} v) + Q_r &= (\varphi_{rr} + \frac{\varphi_r}{r^2} v) + \frac{\sin(2\varphi)}{2r^2} \varphi_r, \quad r \in [0, 1], \\
   w_t + w w_z - \nu w_{zz} + R_z &= 0, \quad z \in [0, 1], \\
   \frac{1}{r}(r v)_r + w_z &= 0, \quad (r, z) \in [0, 1] \times [0, 1], \\
   \varphi_t + v \varphi_r &= \varphi_{rr} + \frac{\varphi_r}{r^2} - \frac{\sin(2\varphi)}{2r^2}, \quad r \in [0, 1].
\end{aligned}
\]  

(2.6)

The initial condition for \((v, w, \phi)\) reduces to
\[
\begin{aligned}
   v|_{t=0} &= r, \quad 0 \leq r \leq 1, \\
   w|_{t=0} &= -2z, \quad 0 \leq z \leq 1, \\
   \varphi|_{t=0} &= \varphi_0(r), \quad 0 \leq r \leq 1,
\end{aligned}
\]

(2.7)

for some \(\varphi_0 \in C^\infty([0, 1])\), with \(\varphi_0(0) = 0\). The boundary condition is
\[
\begin{aligned}
   v(0, t) &= 0, & w(0, t) &= 0, & \varphi(0, t) &= 0, \\
   v(1, t) &= 1, & w(1, t) &= -2, & \varphi(1, t) &= \varphi_0(1).
\end{aligned}
\]

(2.8)

**Remark 2.2** It is easy to verify that the initial and boundary condition (2.7)- (2.8) for \((v, w, \phi)\) is equivalent to the initial condition (1.3) and the boundary condition (1.4) for \((u, d)\).

Now, we are ready to state our main results on the system (2.6), under the initial and boundary condition (2.7) and (2.8). The first result asserts that for any short time smooth solution \((v, w, \varphi, Q, R)\) to (2.6) along with the initial-boundary condition (2.7) and (2.8), \((v, w)\) is static and \(Q, R\) are also static (up to a time-dependent constant). In fact, we have

**Lemma 2.3** For \(0 < T \leq +\infty\), suppose that \(v, w \in C^\infty([0, 1] \times [0, T])\) satisfies
\[
\frac{1}{r}(rv)_r + w_z = 0, \quad (r, z) \in [0, 1] \times [0, 1],
\]

(2.9)

and
\[
\begin{aligned}
   v(0, t) &= 0, & w(0, t) &= 0, \\
   v(1, t) &= 1, & w(1, t) &= -2.
\end{aligned}
\]

(2.10)

Then \(v(r, t) = r\) for any \((r, t) \in [0, 1] \times [0, T]\), and \(w(z, t) = -2z\) for any \((z, t) \in [0, 1] \times [0, T]\).

**Proof.** Differentiating (2.9) with respect to \(z\) yields
\[
w_{zz}(z, t) = 0
\]

so that \(w(z, t) = a_1(t)z + a_2(t)\) for some functions \(a_1(t)\) and \(a_2(t)\). Since \(w(0, t) = 0\) and \(w(1, t) = -2\), we see that \(a_2(t) \equiv 0\) and \(a_1(t) \equiv -2\). Thus \(w(z, t) = -2z\).

Similarly, differentiating (2.9) with respect to \(r\) yields
\[
\left(\frac{1}{r}(rv)_r\right)_r(r, t) = 0,
\]

this implies that \(rv(r, t) = b_1(t)r^2 + b_2(t)\) for some functions \(b_1(t)\) and \(b_2(t)\). Since \(v(0, t) = 0\) and \(v(1, t) = 1\), we see that \(b_2(t) \equiv 0\) and \(b_1(t) \equiv 1\). Thus \(v(r, t) = r\). The proof is complete.

\(\square\)

Next we have
Lemma 2.4 For $0 < T \leq +\infty$, $(v, w, \varphi, Q, R) \in C^\infty([0,1] \times [0,T))$ solves (2.6), under (2.7) and (2.8) iff $v(r, t) = r$, $w(z, t) = -2z$,
\[
\begin{cases}
R(z, t) = -2z^2 + c_1(t) \\
Q(r, t) = -\int_0^r \left( \varphi_{rr} + \frac{\varphi_r}{r} - \frac{\sin(2\varphi)}{2r^2} \right) \varphi_r dr - \frac{r^2}{2} + c_2(t),
\end{cases}
\]
for some $c_1, c_2 \in C^\infty([0,T))$, and
\[
\begin{align*}
\varphi_t + r\varphi_r &= \varphi_{rr} + \frac{\varphi_r}{r} - \frac{\sin(2\varphi)}{2r^2}, \\ 
\varphi(r, 0) &= \varphi_0(r), \\ 
\varphi(0, t) &= 0, \quad \varphi(1, t) = \varphi(1), 
\end{align*}
\]
for some $c_1, c_2 \in C^\infty([0,T))$.

Proof. Applying lemma 2.3 to (2.6) yields that
\[
R_z + 4z = 0,
\]
this, by integration, implies
\[
R(z, t) = -2z^2 + c_1(t),
\]
for some function $c_1 \in C^\infty([0,T))$. Apply lemma 2.3 to (2.6) yields
\[
Q_r = -\left( \varphi_{rr} + \frac{\varphi_r}{r} - \frac{\sin(2\varphi)}{2r^2} \right) \varphi_r - r,
\]
(2.13)
\[
\varphi_t + r\varphi_r = \varphi_{rr} + \frac{\varphi_r}{r} - \frac{\sin(2\varphi)}{2r^2}.
\]
(2.14)
Integrating (2.13) yields (2.11), while (2.11) follows from (2.14), (2.7), and (2.8).

It is readily seen that whether (2.6), under (2.7) and (2.8), admits a global smooth solution is equivalent to whether (2.12) admits a global smooth solution. For this, we are able to extend Chang-Ding [2] and Chang-Ding-Ye [3] on the heat flow of harmonic maps and obtain the following two results.

Theorem 2.5 Suppose $\varphi_0 \in C^\infty([0,1])$ satisfies $\varphi_0(0) = 0$ and $|\varphi_0(r)| \leq \pi$ for all $r \in [0,1]$. Then there is a unique, global smooth solution $(v, w, \varphi)$ to (2.6), under (2.7) and (2.8).

Theorem 2.6 There exists $\varphi_0 \in C^\infty([0,1])$, with $\varphi_0(0) = 0$ and $|\varphi_0(1)| > \pi$, such that the short time smooth solution $(v, w, \varphi)$ to (2.6), under (2.7) and (2.8), must blow up at $T_0$ for some $0 < T_0 = T_0(\phi_0) < +\infty$. More precisely, $\varphi_r(0, t) \to \infty$ as $t \to T_0$.

Remark 2.7 It is readily seen that Theorem 1.1 follows directly from Theorem 2.6. Since $\varphi(r, t)$ blows up at $r = 0$ and $t = T_0$, we see that $d(r, \theta, z, t)$ blows up at $r = 0$, $z \in [0,1]$, and $t = T_0$. Thus the singular set of $d$ at the first singular time $T_0$ includes the line segment $\{0\} \times [0,1] \subset \Omega$.

The proofs of Theorem 2.5 and Theorem 2.6 will be given in Section 4 and Section 5 respectively.
3 Existence of short time smooth solutions

In this section we will establish the existence of short time smooth solutions to the system (2.6), under the initial and boundary conditions (2.7) and (2.8). By lemma (2.4) it suffices to prove the local solvability of the drifted-harmonic map equation (2.12).

Theorem 3.1 (local existence) For any \( \varphi_0 \in C^\infty([0,1]) \), with \( \varphi_0(0) = 0 \), there exist \( t_0 > 0 \) and a unique smooth solution \( \varphi(r,t) \) on \([0,1] \times [0,t_0]\) to the equation (2.12).

Proof. First observe that if \( \varphi \) solves (2.12), then
\[
d(x,y,t) := \left( \sin \varphi(\sqrt{x^2 + y^2},t) \frac{x}{\sqrt{x^2 + y^2}}, \sin \varphi(\sqrt{x^2 + y^2},t) \frac{y}{\sqrt{x^2 + y^2}}, \cos \varphi(\sqrt{x^2 + y^2},t) \right),
\]
for \((x,y) \in B_1^2 \) and \( t \geq 0 \), solves
\[
d_t + (x,y) \cdot \nabla d = \Delta d + |\nabla d|^2 d, \quad (x,y) \in B_1^2, \quad t > 0,
\]
with the initial condition
\[
d|_{t=0} = \left( \sin \varphi_0(\sqrt{x^2 + y^2}) \frac{x}{\sqrt{x^2 + y^2}}, \sin \varphi_0(\sqrt{x^2 + y^2}) \frac{y}{\sqrt{x^2 + y^2}}, \cos \varphi_0(\sqrt{x^2 + y^2}) \right), \quad (3.2)
\]
and the boundary condition
\[
d|_{\partial B_1^2} = (\sin \varphi_0(1)x, \sin \varphi_0(1)y, \cos \varphi_0(1)). \quad (3.3)
\]

By the standard contraction mapping theorem, we can prove that there exist \( t_0 > 0 \) and a unique smooth solution \( d \in C^\infty(B_1^2 \times [0,t_0),S^2) \) to (3.1), along with (3.2) and (3.3) (see, e.g., [26] Section 3 for a detailed proof).

Now we need to argue that such a solution \( d(x,y,t) \) to (3.1)-(3.2)-(3.3) is axisymmetric, i.e.,
\[
d(x,y,t) := d(r,\theta,t) = (\sin \varphi(r,t) \cos \theta, \sin \varphi(r,t) \sin \theta, \cos \varphi(r,t)). \quad (3.4)
\]
Assume (3.4) is true. Then a straightforward calculation as in Section 2 implies that \( \varphi \) solves (2.12). To see (3.4), first note that we can always write
\[
d(x,y,t) = (\sin \varphi(r,\theta,t) \cos \chi(r,\theta,t), \sin \varphi(r,\theta,t) \sin \chi(r,\theta,t), \cos \varphi(r,\theta,t)) \quad (3.5)
\]
for a pair of functions \( \varphi \) and \( \chi \). For \( \alpha \in [0,2\pi]\), let \( R_\alpha \in \text{SO}(3) \) be the rotation map in \( \mathbb{R}^3 \) of angle \( \alpha \) with respect to the \( z \)-axis, and \( S_\alpha \in \text{SO}(2) \) be the rotation map in \( \mathbb{R}^2 \) of angle \( \alpha \) with respect to 0. Since the initial and boundary values \( d_0 \) of \( d \) are axisymmetric, i.e., for any \( \alpha \in [0,2\pi]\),
\[
d_0(S_\alpha(x,y)) = R_\alpha \circ d_0(x,y), \quad (x,y) \in \overline{B_1^2},
\]
we can check that \( R_\alpha^{-1} \circ d(S_\alpha(x,y),t) \), \( \forall \alpha \in [0,2\pi]\), also solves the initial and boundary value problem of the drifted harmonic map equation (2.12). By the uniqueness of solutions to (2.12), this implies that
\[
d(x,y,t) = R_\alpha^{-1} \circ d(S_\alpha(x,y),t), \quad \forall \alpha \in [0,2\pi], \quad (x,y) \in B_1^2,
\]
or equivalently,
\[
d(x,y,t) = (\sin \varphi(r,t) \cos(\eta(r,t) + \theta), \sin \varphi(r,t) \sin(\eta(r,t) + \theta), \cos \varphi(r,t)). \quad (3.6)
\]
for some functions \( \varphi(r,t) \) and \( \eta(r,t) \). Direct calculations, similar to Section 2, imply that \( \varphi \) and \( \eta \) satisfy
\[
\begin{align*}
\varphi_t + r \varphi_r &= (\varphi_{rr} + \frac{\varphi_r}{r}) - (\eta^2 + \frac{1}{r}) \sin \varphi \cos \varphi, \\
\sin \varphi (\eta_t + r \eta_r) &= \sin \varphi (\eta_{rr} + \frac{\eta_r}{r}) + 2 \varphi_r \eta_r \cos \varphi.
\end{align*}
\] (3.7)

Now we need to show

Claim 1. \( \eta(r,t) = 0 \) for \((r,t) \in [0,1] \times [0,t_0)\).

Note that when \( \sin \varphi(r,t) = 0 \), we can simply define \( \eta(r,t) = 0 \) because any value of \( \eta(r,t) \) gives the same value of \( d \) by (3.6). Set
\[ U = \{(r,t) \in [0,1] \times [0,t_0) \mid \sin \varphi(r,t) \neq 0\}, \]
and define
\[ h(r,t) = \eta(r,t) \sin \varphi(r,t), \quad (r,t) \in U. \]

Then by (3.7), \( h(r,t) \) satisfies
\[
h_t + rh_r = h_{rr} + \frac{h_r}{r} + \left[\varphi^2_r - (\eta^2_r + \frac{1}{r^2}) \cos^2 \varphi\right] h,
\] (3.8)

under the initial and boundary conditions:
\[ h(r,t) = 0, \text{ on } \partial U \cap \{0 \leq t < t_0\}. \] (3.9)

Since \( \varphi_r \) is bounded in \( U \), replacing \( h \) by \( he^{-ct} \) for a sufficiently large \( c > 0 \) we may assume the coefficient of \( h \) in (3.8) is negative. Therefore by the maximum principle, we conclude that \( h \equiv 0 \) and consequently \( \eta \equiv 0 \) on \( U \) (see [2] Lemma 2.2, or [12] and [37]). Hence Claim 1 holds and the proof of Theorem 3.1 is complete.

4 Existence of global smooth solutions and proof of Theorem 2.5

This section is devoted to the proof of Theorem 2.5 on the existence of global smooth solutions when the initial data \( \varphi_0 \) satisfies \( \varphi_0(0) = 0 \) and \( |\varphi_0(r)| \leq \pi \) for all \( r \in [0,1] \). The proof is motivated by [2].

We start with

Lemma 4.1 (maximum principle) For any smooth solution \( \varphi(r,t) : [0,1] \times [0,T) \to \mathbb{R} \) to the drifted harmonic map equation (2.12), if
\[ \varphi_0(0) = 0, \quad -\pi \leq \varphi_0(r) \leq \pi, \quad \forall \ r \in [0,1], \]
then
\[ -\pi < \varphi(r,t) < \pi, \quad \forall \ r \in (0,1) \text{ and } t \in (0,T). \] (4.1)

Proof. We only present the proof for \( \varphi < \pi \), since the other half of the inequality (4.1) can be proved similarly. Set \( \tilde{\varphi} = \pi - \varphi \). Then \( \tilde{\varphi} \) satisfies
\[
\tilde{\varphi}_t + r \tilde{\varphi}_r = \tilde{\varphi}_{rr} + \frac{\tilde{\varphi}_r}{r} + p_1(r,t)\tilde{\varphi},
\] (4.2)
where

\[ p_1(r, t) := \frac{\sin(2 \tilde{\varphi})}{2 \tilde{\varphi} r^2}, \]

and

\[ \tilde{\varphi}(r, 0) \geq 0, \quad \tilde{\varphi}(1, t) \geq 0 \quad \text{and} \quad \tilde{\varphi}(0, t) = \pi. \]

Thus for any \( t \in (0, T) \), there exists a small \( r_1 \in (0, 1) \) such that \( \tilde{\varphi}(r, \tau) > 0 \) for any \( (r, \tau) \in (0, r_1] \times (0, t] \). On \( (r_1, 1) \times (0, t] \), by the fact that \( p_1(r, \tau) \) is bounded, we can prove \( \tilde{\varphi} > 0 \) by the standard maximum principle (see [12] or [37]). Therefore, we conclude that \( \tilde{\varphi} > 0 \) or equivalently \( \varphi < \pi \) on \( (0, 1) \times (0, T) \).

\[ \text{Lemma 4.2 (comparison principle) Suppose the functions } \varphi, f \text{ and } g \text{ are smooth solution, sub-}\]

solution and supersolution to (2.14) on \([0, 1] \times [0, T]\) respectively, and

\[ f(r, t) \leq \varphi(r, t) \leq g(r, t) \text{ on } ([0, 1] \times \{0\}) \cup ([0, 1] \times (0, T)). \]

Then we have

\[ f(r, t) \leq \varphi(r, t) \leq g(r, t), \quad \forall \ (r, t) \in [0, 1] \times [0, T). \]

\[ \text{Proof.} \quad \text{Set } \bar{f} = f - \varphi. \text{ Then } \bar{f} \text{ satisfies} \]

\[ \bar{f}_t + r \bar{f}_r \geq \bar{f}_{rr} + \frac{\bar{f}_r}{r} + p_2(r, t) \bar{f}, \]

where

\[ p_2(r, t) := -\frac{\sin(2 f(r, t)) - \sin(2 \varphi(r, t))}{2 r^2 (f(r, t) - \varphi(r, t))}, \]

and

\[ \bar{f}(r, t) \leq 0 \text{ on } ([0, 1] \times \{0\}) \cup ([0, 1] \times (0, T)). \]

For any \( t \in (0, T) \), there exists a small \( r_2 \in (0, 1) \) such that \( p_2(r, \tau) < 0 \) on \( (r_2, 1) \times (0, t) \). Combining with the fact \( p_2(r, \tau) \) is bounded on \( (r_2, 1) \times (0, t) \), we conclude that \( p_2(r, \tau) \) is bounded from above on \( (r, \tau) \in (0, 1) \times (0, t) \). By the standard maximum principle (see [12] or [37]), we conclude that \( \bar{f} \leq 0 \) or \( \varphi \geq f \) on \([0, 1] \times (0, T)\). Similarly, one can prove \( \phi \leq g \).

\[ \text{Proof of Theorem 2.5.} \quad \text{To prove the existence of global smooth solutions of (2.12), we need to construct suitable supersolutions and subsolutions to (2.14). Denote} \]

\[ \overline{\varphi}(r, c) = 2 \arctan \left( \frac{r}{c} \right) \quad \text{and} \quad \underline{\varphi}(r, c) = 2 \arctan \left( -\frac{r}{c} \right), \]

for some positive constant \( c \). It is easy to see that \( \overline{\varphi}(r, c) \) and \( \underline{\varphi}(r, c) \) are smooth functions in \([0, 1]\]. Direct calculations give

\[ \overline{\varphi}_t + r \overline{\varphi}_r - \overline{\varphi}_{rr} - \frac{\overline{\varphi}_r}{r} - \frac{\sin(2 \overline{\varphi})}{2 r^2} = \frac{2rc}{c^2 + r^2} \geq 0, \quad r \in [0, 1]. \]

Thus \( \overline{\varphi} \) is a supersolution of (2.14). Denote

\[ \eta_0 = \pi - \max_{0 \leq r \leq 1} |\varphi_0(r)|. \]
By the assumption on \(\varphi_0\), we have \(\eta_0 \geq 0\) and \(|\varphi_0| \leq \pi - \eta_0\). Since \(\varphi_r(0, c) = \frac{2}{c}\) and \(\varphi(0, c) = \varphi_0(0) = 0\), we can find a sufficiently small \(c > 0\) such that
\[
\varphi(r, c) \geq \varphi_0(r) > 0 \quad (4.7)
\]
for any \(r \in [0, 1]\), with equality iff \(r = 0\). Similarly, we can prove that \(\varphi(r, c)\) is a subsolution to (2.14) and
\[
\varphi_0(r) \geq \varphi(r, c) \text{ in } [0, 1] \quad (4.8)
\]
for a sufficiently small \(c > 0\). By lemma 4.2, we can conclude that \(\varphi(r, c) \geq \varphi(r, t) \geq \varphi(r, c)\) for \(r \in [0, 1]\) and \(t > 0\).

Suppose \(T > 0\) is the maximum time interval for \(\varphi\). For any \(r_0 \in (0, 1)\) and \(t_1 \in (0, T)\), by the standard regularity theory of parabolic equations, we can prove
\[
\|\varphi\|_{C^k([r_0, 1] \times (t_1, T))} \leq C r_0^{-k}, \forall k \geq 1. \quad (4.9)
\]
This implies that the possible singularity of the solution \(\varphi\) can only happen at \(r = 0\). Suppose \(T < +\infty\). Then
\[
d(x, y, t) = (\sin \varphi \cos \theta, \sin \varphi \sin \theta, \cos \varphi)
\]
bloows up at \(((0, 0), T)\). By the standard blowing up argument (cf. [26] Theorem 1.3), there exist \((x_m, y_m) \to (0, 0), t_m \uparrow T, r_m \downarrow 0\) as \(m \to +\infty\) and a nonconstant smooth harmonic map \(\omega : \mathbb{R}^2 \to S^2\) such that
\[
d_m(x, y, t) := d(r_m x, r_m y, t_m + r_m^2 t) \to \omega \quad \text{in } C^2_{\text{loc}}(\mathbb{R}^2 \times (-\infty, 0]). \quad (4.10)
\]
Since, by lemma 4.1,
\[-\pi < \varphi(r, t) < \pi, \quad r \in [0, 1], \quad t_m \leq t < T,
\]
we have that the third component, \(\omega^3\), of \(\omega\) satisfies
\[-1 < \omega^3(x, y) < 1 \quad \text{for any } (x, y) \in \mathbb{R}^2.
\]
This implies that \(\omega \in C^\infty(\mathbb{R}^2, S^2)\) is a nontrivial harmonic map, with finite energy and degree zero, which is impossible. Therefore, we conclude that \(T = +\infty\). This proves Theorem 2.5. \(\Box\)

5 Finite time singularity and proof of Theorem 2.6

In this section, we will modify the construction by [3] to show the existence of solutions with finite time singularity of (2.12) for some suitably chosen initial data \(\varphi_0\) with \(\varphi_0(0) = 0\) and \(|\varphi_0(1)| > \pi\).

Proof of Theorem 2.6 We adopt some ideas of [3] to construct suitable barrier functions from below. Without loss of generality, we assume that \(\varphi_0(1) > \pi\). Denote the scalar-valued tension field by
\[
\tau(\phi) := \phi_{rr} + \frac{1}{r} \phi_r - \frac{\sin \phi \cos \phi}{r^2}.
\]
There are a family of smooth solutions of \(\tau(\phi) = 0\), with \(\phi(0) = 0\) and \(\phi(r) > 0\), given by
\[
\phi(r, \beta) = \arccos \left(\frac{\beta^2 - r^2}{\beta^2 + r^2}\right) \quad \text{or} \quad \phi(r, \beta) = 2 \arctan \left(\frac{r}{\beta}\right) \quad (5.1)
\]
for \(\beta > 0\).
In order to handle the drift term $r\varphi_r$ in the equation (2.14), we need to reparameterize $\beta$ by $e^t\beta$ in (5.1):

$$\phi(r, \beta, t) = \arccos\left(\frac{e^{2t}\beta^2 - r^2}{e^{2t}\beta^2 + r^2}\right) \quad \text{or} \quad \phi(r, \beta, t) = 2 \arctan\left(\frac{r}{e^{t}\beta}\right),$$  \hspace{1cm} (5.2)

which is also a solution of $\tau(\phi) = 0$ for any $t \in [0, +\infty)$. For any $\varepsilon \in (0,1)$ and $\mu > 0$, let $a = 1 + \varepsilon$ and

$$\theta(r, \mu, t) = 2 \arctan\left(\frac{a}{e^{at}\mu}\right).$$  \hspace{1cm} (5.3)

Then $\theta(r, \mu, t)$ satisfies

$$\theta_{rr} + \frac{1}{r} \theta_r - \frac{a^2 \sin \theta \cos \theta}{r^2} = 0.$$  \hspace{1cm} (5.4)

Choosing $\mu$ large enough so that $\theta(r, \mu, t)$ is small enough and

$$\cos \theta(r, \mu, t) \geq \frac{1}{1 + \varepsilon}$$  \hspace{1cm} (5.5)

for any $r \in [0, 1]$ and $t \in [0, +\infty)$. We will look for a subsolution $f$ of (2.14) in the form:

$$f(r, t) = \phi(r, \beta(t), t) + \theta(r, \mu, t),$$  \hspace{1cm} (5.6)

where $\beta(t)$ solves

$$\begin{cases}
\frac{d\beta}{dt} = -\delta e^{-2t}\beta^\varepsilon, \\
\beta(0) = \beta_0,
\end{cases}$$  \hspace{1cm} (5.7)

where $\delta$ and $\beta_0$ are positive constants to be determined later.

**Claim 2.** If $0 < 2\beta_0^{1-\varepsilon} < \delta(1 - \varepsilon)$, then there exists $0 < T_0 < +\infty$ such that

$$\lim_{t \uparrow T_0^-} f_r(0, t) = +\infty.$$  \hspace{1cm} (5.8)

To see (5.8), we solve the ordinary differential equation (5.7) and obtain

$$\beta^{1-\varepsilon} = \frac{\delta(1 - \varepsilon)}{2}(e^{-2t} - 1) + \beta_0^{1-\varepsilon}.$$  \hspace{1cm} (5.9)

Set

$$T_0 := \frac{1}{2} \ln \left(\frac{\delta(1 - \varepsilon)}{\delta(1 - \varepsilon) - 2\beta_0^{1-\varepsilon}}\right) > 0.$$  \hspace{1cm}

Then

$$\beta(t) \to 0 \quad \text{as} \quad t \to T_0^-.$$  \hspace{1cm}

By (5.12) below, we have

$$f_r(r, t) = \frac{2\beta e^t}{e^{2t}\beta^2 + r^2} + \frac{2a\mu r^\varepsilon e^{at}}{\mu^2 e^{2at} + r^{2a}},$$

so that

$$f_r(0, t) = \frac{2}{e^t\beta(t)} \to +\infty, \quad \text{as} \quad t \to T_0^-.$$  \hspace{1cm}

**Claim 3.** There exists $\delta > 0$ such that $f$ is a subsolution of (2.12), i.e., $f$ satisfies

$$f_t + rf_r \leq \tau(f).$$
In fact, by (5.1) and (5.4), we have
\[
\tau(f) = \frac{1}{r^2} [a^2 \sin \theta \cos \theta - \cos(2\phi + \theta) \sin \theta] \\
\geq \frac{1}{r^2} [(1 + \varepsilon) \sin \theta - \cos(2\phi + \theta) \sin \theta] \\
\geq \frac{\varepsilon \sin \theta}{r^2} = \frac{2\mu e^{-at} \varepsilon}{\mu^2 + e^{-2at} r^2} \\
\geq \frac{2\mu e^{-at} \varepsilon}{\mu^2 + 1} r^{-1}
\]
where we have used (5.5) and (5.3). From (5.1) and (5.3), we have
\[
f_t = -\frac{2re^t (\beta + \beta t)}{e^{2t} \beta^2 + r^2} - \frac{2a\mu e^{at}}{\mu^2 e^{2at} + r^2}
\]
and
\[
f_r = \frac{2\beta e^t}{e^{2t} \beta^2 + r^2} + \frac{2a\mu e^{-at} \varepsilon}{\mu^2 e^{2at} + r^2}
\]
Combining (5.11) with (5.12) and using (5.7), we obtain
\[
f_t + rf_r = -\frac{2re^t \beta t}{e^{2t} \beta^2 + r^2} = \frac{2\delta e^{-t} \beta \varepsilon}{e^{2t} \beta^2 + r^2}
\]
To prove Claim 3, it suffices to verify the following inequality:
\[
\frac{2\delta re^{-t} \beta \varepsilon}{e^{2t} \beta^2 + r^2} \leq \frac{2\gamma \mu e^{-at} \varepsilon}{\mu^2 + 1} r^{-1}.
\]
Let \( s = \frac{r}{e^{\beta t}} \). Then (5.14) is equivalent to
\[
\frac{s^2 - \varepsilon}{1 + s^2} \leq \frac{\gamma \mu \varepsilon}{\delta (\mu^2 + 1)} \quad \forall s > 0.
\]
It is easy to check that the function \( \frac{s^2 - \varepsilon}{1 + s^2} \) has a maximum \( M(\varepsilon) \) depending only on \( \varepsilon \). Therefore, if we choose
\[
\delta \leq \frac{\gamma \mu \varepsilon}{M(\varepsilon)(\mu^2 + 1)}
\]
then (5.14) holds and hence the Claim 3 follows.

Claim 4. For sufficiently large \( \mu > 0 \), there exists \( \varphi_0 \in C^\infty([0, 1]) \), with \( \varphi_0(0) = 0 \) and \( \varphi_0(1) > \pi \), such that
\[
f(r, t) \leq \varphi_0(r) \text{ on } ([0, 1] \times \{0\}) \cup ([0, 1] \times (0, T_0)).
\]
Since \( \varphi_0(1) > \pi \), we can choose a sufficiently large \( \mu \) such that \( \theta(1, \mu, t) \leq \varphi_0(1) - \pi \) for any \( t \geq 0 \). This, combined with \( 0 < \phi(1, \beta, t) < \pi \), implies
\[
f(1, t) = \phi(1, \beta, t) + \theta(1, \mu, t) \leq \varphi_0(1), \quad \forall 0 \leq t < T_0.
\]
It is clear that we can find some initial data \( \varphi_0 \in C^\infty([0,1]) \), with \( \varphi_0(0) = 0 \) and \(|\varphi_0(1)| > \pi \), such that \( \varphi_0(r) \geq f(r,0) \) for any \( r \in [0,1] \). Hence (5.16) holds.

It follows from Claim 3, Claim 4, and lemma 4.2 that
\[
f \leq \varphi, \quad \text{in } [0,1] \times [0,T_0].
\]
This, combined with \( f(0,t) = \varphi(0,t) = 0 \), implies that \( \varphi_r(0,t) \geq f_r(0,t) \) for \( 0 \leq t < T_0 \). Hence, by Claim 2, we have
\[
\varphi_r(0,t) \to +\infty, \quad \text{as } t \to T_0^-.
\]
This completes the proof of Theorem 2.6.

\[ \square \]

**Remark 5.1** It is clear that the Claim 3 doesn’t hold if the time relaxation constant \( \gamma = 0 \). In fact, it is a very challenging question how to construct solutions with finite time singularity to (2.6) when \( \gamma = 0 \). Such an example would shed lights to the question whether the equation of viscoelastic flows admits finite time singularity in dimension three.

We finish this section with two remarks on Theorem 1.1.

**Remark 5.2** Under the same assumptions as Theorem 1.1, does the stress tensor \( \mathcal{S} := \nabla d \circ \nabla d - \frac{1}{2} |\nabla d|^2 I_3 \) blow up as \( t \) approaches \( T_0 \)?

By calculating the stress tensor for the corresponding subsolution, we conjecture that \( \mathcal{S} \) doesn’t blow up. Here we sketch the calculation. Assume \((u,d,P)\) is given by Theorem 1.1, and \( f \) is given by Section 5 above. Set
\[
\tilde{d} = (\sin f \cos \theta, \sin f \sin \theta, \cos f).
\]
Then direct calculations imply
\[
\nabla \tilde{d} \circ \nabla \tilde{d} = \left( \begin{array}{ccc}
  f_r^2 \cos \theta^2 + \frac{\sin^2 f}{r^2} \sin^2 \theta & (f_r^2 - \frac{\sin^2 f}{r^2}) \cos \theta \sin \theta \\
  (f_r^2 - \frac{\sin^2 f}{r^2}) \cos \theta \sin \theta & f_r^2 \sin^2 \theta + \frac{\sin^2 f}{r^2} \cos^2 \theta
\end{array} \right)
\]
and
\[
|\nabla \tilde{d}|^2 = f_r^2 + \frac{\sin^2 f}{r^2}.
\]
At \( r = 0 \): since \( \frac{\sin f}{r} = f_r = \frac{2}{\beta(t)} e^{-t} \), it follows that
\[
\nabla \tilde{d} \circ \nabla \tilde{d} \bigg|_{r=0} = \left( \begin{array}{ccc}
  \frac{4}{\beta^2(t)} & 0 \\
  0 & \frac{4}{\beta^2(t)}
\end{array} \right) e^{-2t}
\]
and
\[
|\nabla \tilde{d}|^2 \bigg|_{r=0} = \frac{8}{\beta^2(t)} e^{-2t}.
\]
Therefore the stress tensor for \( \tilde{d} \) at \( r = 0 \) is
\[
\tilde{\mathcal{S}} := \left( \nabla \tilde{d} \circ \nabla \tilde{d} - \frac{1}{2} |\nabla \tilde{d}|^2 I_2 \right) \bigg|_{r=0} = \left( \begin{array}{ccc}
  0 & 0 \\
  0 & 0
\end{array} \right),
\]
where \( I_2 \) is the identity matrix of order 2.
Remark 5.3 Under the same assumptions as Theorem 1.1 does the solution \((u, d, P)\) satisfy the energy dissipation inequality

\[
\frac{d}{dt} \left( \frac{1}{2} \int_{\Omega} |u|^2 + |\nabla d|^2 \right) + \int_{\Omega} \left( |\nabla u|^2 + |\Delta d + |\nabla d|^2 d|^2 \right) \leq 0,
\]

for \(0 \leq t < T_0\)?

Since \(u(x, y, z, t) = u_0(x, y, z) = (x, y, -2z)\) in \(\Omega = B^2_1 \times [0, 1]\), direct calculations imply

\[
\frac{d}{dt} \int_{\Omega} |u|^2 = 0, \quad \int_{\Omega} \Delta u \cdot u = 0,
\]

\[
\int_{\Omega} \langle u \cdot \nabla u, u \rangle = \int_{\Omega} u \cdot \nabla \left( \frac{|u|^2}{2} \right) = \int_{\Omega} (x^2 + y^2 - 8z^2) = -\frac{13}{6} \pi,
\]

and

\[
\int_{\Omega} |\nabla u|^2 = 6\pi.
\]

(1.1) can be rewritten as

\[
\nabla \left( \frac{x^2}{2} + \frac{y^2}{2} + 2z^2 + P \right) = -\langle \Delta d, \nabla d \rangle.
\]

(5.23)

Multiplying (5.23) by \(u\) and integrating over \(\Omega\) yields

\[
\frac{13}{6} \pi - \int_{\partial\Omega} Pu \cdot \nu = \int_{\Omega} \langle \Delta d, u \cdot \nabla d \rangle.
\]

(5.24)

Since the boundary condition of \(d\) on \(\partial\Omega\) is given by

\(d = d_0\) on \(\partial B^2_1 \times [0, 1], \quad \frac{\partial d}{\partial \nu} = 0\) on \(B^2_1 \times \{0, 1\}\),

multiplying (1.1) by \(\Delta d\) and integrating over \(\Omega\) we would have

\[
- \frac{d}{dt} \left( \frac{1}{2} \int_{\Omega} |\nabla d|^2 \right) + \int_{\Omega} \langle u \cdot \nabla d, \Delta d \rangle = \int_{\Omega} ||\Delta d + |\nabla d|^2 d|^2 ||.
\]

(5.25)

Adding (5.24) and (5.25) together, we have

\[
\frac{d}{dt} \left( \frac{1}{2} \int_{\Omega} |u|^2 + |\nabla d|^2 \right) + \int_{\Omega} \left( |\nabla u|^2 + |\Delta d + |\nabla d|^2 d|^2 \right)
\]

\[
= 6\pi + \frac{13}{6} \pi - \int_{\partial\Omega} Pu \cdot \nu.
\]

(5.26)

Therefore (5.22) holds iff

\[
6\pi + \frac{13}{6} \pi - \int_{\partial\Omega} Pu \cdot \nu \leq 0.
\]

(5.27)

However, it is unclear whether (5.27) holds for the solution by Theorem 1.1.
6 Finite time singularity for generic initial data and proof of Theorem 1.3

This section is devoted to another construction of finite time singularity of (1.1) for more generic initial data, in which the solution satisfies the energy dissipation inequality (5.22).

First we recall the following result on the existence of local smooth solution to (1.1) and (1.8), whose proof can be found in [26].

Lemma 6.1 For \((u_0, d_0) \in C^\infty_{0, \text{div}}(B^3_1, \mathbb{R}^3) \times C^\infty_e(B^3_1, \mathbb{S}^2)\), there exist \(T_0 = T_0(u_0, d_0) > 0\) and a unique smooth solution \((u, d) \in C^\infty(B^3_1 \times [0, T_0), \mathbb{R}^3 \times \mathbb{S}^2)\) to the system (1.1) along with the initial-boundary condition (1.8). Moreover, the energy dissipation inequality (5.22) holds for \(0 \leq t < T_0\).

Now we would like to proceed with the proof of Theorem 1.3 as follows.

Proof. Assume \(T_0 > 0\) is the maximal time interval for the short time smooth solution \((u, d)\) by lemma 6.1. We want to show

Claim 5. If \(\epsilon_0 > 0\) is sufficiently small, then \(T_0 < 1\).

We argue by contradiction. Suppose that Claim 5 were false. Then for any \(\epsilon > 0\) we can find \((u_0, d_0) \in C^\infty_{0, \text{div}}(B^3_1, \mathbb{R}^3) \times C^\infty_e(B^3_1, \mathbb{S}^2)\) such that

(a) \(d_0\) is not homotopic to \(e\) relative to \(\partial B^3_1\),

(b) \(E(u_0, d_0) \leq \epsilon^2\),

and a smooth solution \((u, d) \in C^\infty(B^3_1 \times [0, 1], \mathbb{R}^3 \times \mathbb{S}^2)\) to (1.1) and (1.8). Integrating (5.22) over \(t\) yields that \((u, d)\) satisfies the energy inequality:

\[
E(u(t), d(t)) + \int_0^t \int_{B^3_1} (|\nabla u|^2 + |\Delta d + |\nabla d||^2 d)^2 \leq E(u_0, d_0) \leq \epsilon^2, \tag{6.1}
\]

for all \(0 \leq t \leq 1\). Applying Fubini’s theorem to (6.1), we find that there exists \(t_1 \in (\frac{1}{2}, 1)\) such that

\[
E(u(t_1), d(t_1)) + \int_{B^3_1} (|\nabla u(t_1)|^2 + |\Delta d(t_1) + |\nabla d(t_1)||^2 d(t_1)|^2) \leq 8\epsilon^2. \tag{6.2}
\]

From (6.2) and \(\epsilon\)-apriori estimate (6.6) of Theorem 6.2 below, we conclude that there exists a universal \(C > 0\) such that

\[
[d(t_1)]_{C^2_{\epsilon}(B^3_1)} \leq C\sqrt{\epsilon}. \tag{6.3}
\]

Thus \(d(t_1)(B^3_1) \subset B^3_{C\sqrt{\epsilon}}(e) \cap \mathbb{S}^2\) and hence \(d(t_1)\) is homotopic to \(e\) relative to \(\partial B^3_1\), provided \(\epsilon > 0\) is chosen to be sufficiently small. Since \(d \in C^\infty(B^3_1 \times [0, t_1], \mathbb{S}^2)\) and \(d = e\) on \(\partial B^3_1 \times [0, t_1]\), we see that \(d(t_1)\) is homotopic to \(d_0\) relative to \(\partial B^3_1\) and hence \(d_0\) is homotopic to \(e\) relative to \(\partial B^3_1\). This contradicts the assumption (a). Hence Claim 5 is true. This completes the proof of Theorem 1.3 □

Now we need an \(\epsilon\)-apriori estimate on approximate harmonic maps from \(B^3_1\) to \(\mathbb{S}^2\), which can be proved by suitable modifications of the arguments by Ding-Wang [9] and Lin-Wang [29].

Theorem 6.2 There exist \(\epsilon > 0\) and \(C > 0\) such that if \(d \in C^\infty_e(B^3_1, \mathbb{S}^2)\) satisfies

\[
E(d) := \frac{1}{2} \int_{B^3_1} |\nabla d|^2 \leq \epsilon^2, \tag{6.4}
\]
\[
\int_{B_1^3} |\Delta d + |\nabla d|^2 d|^2 \leq \epsilon^2. \tag{6.5}
\]

Then
\[
[d]_{C^{1/2}(B_1^3)} \leq C\sqrt{\epsilon}. \tag{6.6}
\]

**Proof.** The proof is based on suitable modifications of that by Ding-Wang \[9\] and Lin-Wang \[29\]. For the completeness, we sketch it here. We divide the proof of estimate (6.6) into two lemmas.

**Lemma 6.3** Under the same assumptions as Theorem 6.2, for any fixed \(\delta_0 \in (\epsilon, 1)\) we have that
\[
[d]_{C^{1/2}(B_{r_0}^3(x_0))} \leq C\sqrt{\epsilon}, \tag{6.7}
\]
holds for any \(x_0 \in B_{1-\delta_0}^3\) and \(0 < r_0 < \delta_0\).

**Proof of Lemma 6.3**: In order to show (6.7), set the tension field of \(d\) by
\[
\tau(d) \equiv \Delta d + |\nabla d|^2 : B_3^1 \rightarrow \mathbb{R}^3.
\]
We will first establish a modified energy monotonicity inequality for approximate harmonic maps in dimension three. From (6.5), we see that tension field \(\tau(d) \in L^2(B_3^1)\), and
\[
\|\tau(d)\|_{L^2(B_1^3)} \leq \epsilon. \tag{6.8}
\]

Now we have

**Claim 6.** For any \(x_0 \in B_1^3\) and \(0 < r \leq R < 1 - |x_0|\), it holds
\[
r^{-1} \int_{B_r(x_0)} |\nabla d|^2 \leq 8R^{-1} \int_{B_R(x_0)} |\nabla d|^2 + 8R \int_{B_R(x_0)} |\tau(d)|^2. \tag{6.9}
\]

To see (6.9), we assume for simplicity that \(x_0 = 0\). Multiplying the approximate harmonic map equation
\[
\Delta d + |\nabla d|^2 d = \tau(d), \quad \text{in } B_1^3, \tag{6.10}
\]
by \(x \cdot \nabla d\), integrating the resulting equation over \(B_r\) for \(0 < r < 1\), and applying the same argument as \[29\] lemma 5.3, we obtain
\[
\frac{d}{dr} \left( r^{-1} \int_{B_r(0)} \left( \frac{1}{2} |\nabla d|^2 - \langle \tau(d), x \cdot \nabla d \rangle \right) \right) = r^{-1} \int_{\partial B_r(0)} \left( \frac{\partial d}{\partial r} \right)^2 - \int_{\partial B_r(0)} \langle \tau(d), \frac{\partial d}{\partial r} \rangle. \tag{6.11}
\]

Thus (6.9) follows by integrating (6.11) over \(r\) and Hölder’s inequality.

It follows from (6.4), (6.5), and (6.9) that
\[
\sup \left\{ r^{-1} \int_{B_r(x)} |\nabla d|^2 : x \in B_{1-\delta_0}^3, \ 0 < r \leq \delta_0 \right\} \leq 8\delta_0^{-1} \int_{B_1^3} |\nabla d|^2 + 8\delta_0 \int_{B_1^3} |\tau(d)|^2 \leq C\epsilon^2(1 + \delta_0^{-1}) \leq C\epsilon. \tag{6.12}
\]

Next we have
Claim 7. For any $\alpha \in (0, \frac{1}{2}]$, there exists $\theta_0 \in (0, \frac{1}{2})$ such that for any $x_0 \in B_{1-\delta_0}^3$ and $0 < r < \delta_0$, it holds

$$
(\theta_0 r)^{-1} \int_{B_{\theta_0 r}(x_0)} |\nabla d|^2 \leq \theta_0^{2\alpha} r^{-1} \int_{B_{r}(x_0)} |\nabla d|^2 + C \theta_0^{-1} r \int_{B_{r}(x_0)} |\tau(d)|^2.
$$

(6.13)

To show (6.13), first recall the Morrey space $M^{2,2}(U)$ for $U \subset \mathbb{R}^3$:

$$
M^{2,2}(U) := \left\{ f \in L^2_{\text{loc}}(U) \mid \|f\|_{M^{2,2}(U)} := \sup_{B_{r}(x) \subset U} r^{-1} \int_{B_{r}(x)} |f|^2 < +\infty \right\}.
$$

From (6.12), we have that $\nabla d \in M^{2,2}(B_{\delta_0}(x))$ for any $x \in B_{1-\delta_0}^3$, and

$$
\|\nabla d\|_{M^{2,2}(B_{\delta_0}(x))} \leq C, \quad \forall x \in B_{1-\delta_0}^3.
$$

(6.14)

For $x_0 \in B_{1-\delta_0}^3$ and $0 < r < 1 - \delta_0$, let $\tilde{d \in H^1(\mathbb{R}^3, \mathbb{R}^3)}$ be an extension of $d$ such that $\tilde{d} - d$ in $B_{r}(x_0)$, $|\tilde{d}(x)| \leq 2$ for $x \in \mathbb{R}^3$, and

$$
\begin{cases}
\|\nabla \tilde{d}\|_{L^2(\mathbb{R}^3)} \leq C\|\nabla d\|_{L^2(B_r(x_0))}, \\
\|\nabla \tilde{d}\|_{M^{2,2}(\mathbb{R}^3)} \leq C\|\nabla d\|_{M^{2,2}(B_r(x_0))}.
\end{cases}
$$

(6.15)

By the Helmholtz decomposition, there exist $G \in H^1(\mathbb{R}^3)$ and $H \in L^2(\mathbb{R}^3, \mathbb{R}^3)$ such that

$$
\begin{cases}
\nabla \tilde{d} \times \tilde{d} = \nabla G + H, \quad \nabla \cdot H = 0 \quad \text{in} \mathbb{R}^3, \\
\|\nabla G\|_{L^2(\mathbb{R}^3)} + \|H\|_{L^2(\mathbb{R}^3)} \leq C\|\nabla \tilde{d}\|_{L^2(\mathbb{R}^3)} \leq C\|\nabla d\|_{L^2(B_r(x_0))}.
\end{cases}
$$

(6.16)

Applying the Poincaré inequality, the duality between the Hardy space $H^1(\mathbb{R}^3)$ and BMO$(\mathbb{R}^3)$ (see [11], [15], or [29]), we can estimate

$$
\int_{\mathbb{R}^3} |H|^2 = \int_{\mathbb{R}^3} H \cdot (\nabla \tilde{d} \times \tilde{d} - \nabla G) = \int_{\mathbb{R}^3} H \cdot \nabla \tilde{d} \times \tilde{d}
\leq C\|H \cdot \nabla \tilde{d}\|_{H^1(\mathbb{R}^3)}\|\tilde{d}\|_{\text{BMO}(\mathbb{R}^3)}
\leq C\|H\|_{L^2(\mathbb{R}^3)}\|\nabla \tilde{d}\|_{L^2(\mathbb{R}^3)}\|\nabla \tilde{d}\|_{M^{2,2}(\mathbb{R}^3)}
\leq C\|\nabla d\|_{L^2(B_r(x_0))}^2 \|\nabla d\|_{M^{2,2}(B_r(x_0))} \leq \frac{C}{m} \int_{B_r(x_0)} |\tau(d)|^2.
$$

(6.17)

From (6.10), $G$ solves

$$
\Delta G = \tau(d) \times d \quad \text{in} \quad B_r(x_0).
$$

(6.18)

By the standard $L^2$-estimate, we have that for any $0 < \theta < 1$,

$$
\int_{B_{\theta r}(x_0)} |\nabla G|^2 \leq C \theta^3 \int_{B_{r}(x_0)} |\nabla d|^2 + r^2 \int_{B_{r}(x_0)} |\tau(d)|^2.
$$

(6.19)

Putting (6.17) and (6.19) together, we obtain

$$
\frac{1}{\theta r} \int_{B_{\theta r}(x_0)} |\nabla d|^2 \leq C(\theta^2 + \theta^{-1}) \frac{1}{r} \int_{B_{r}(x_0)} |\nabla d|^2 + C \theta^{-1} r \int_{B_{r}(x_0)} |\tau(d)|^2,
$$

(6.20)

for any $x_0 \in B_{1-\delta_0}^3$, $0 < r < \delta_0$, and $0 < \theta < 1$. 

20
For any $0 < \alpha \leq \frac{1}{4}$, first choosing $\theta = \theta_0 \in (0,1)$ such that $C \theta_0^2 \leq \frac{1}{2} \theta_0^{2\alpha}$ and then choosing $\epsilon = \epsilon_0 > 0$ such that $C \theta_0^{-1} \epsilon_0 \leq \frac{1}{2} \theta_0^{2\alpha}$, we obtain (6.13). It is standard that iterations of (6.13) imply that
\[
\frac{1}{s} \int_{B_r(x_0)} |\nabla d|^2 \leq (\frac{s}{r})^{2\alpha} \int_{B_r(x_0)} |\nabla d|^2 + C_s \int_{B_r(x_0)} |\tau(d)|^2,
\]
holds for any $x_0 \in B_1^3$ and $0 < s \leq r < \delta_0$. It is clear that (6.7) follows from (6.21) and Morrey’s decay lemma (cf. [36]).

**Lemma 6.4** Under the same assumptions as in Theorem 6.2, there exists $0 < \delta_0 \leq \frac{1}{2}$ depending only on $\partial B^3_1$ such that for any $x_0 \in \partial B^3_1$ and $0 < r_0 \leq 2 \delta_0$, it holds
\[
[d]_{C^{1/2}(B^3_r(x_0))} \leq C \sqrt{\epsilon},
\]
where $B^+_r(x_0) := B_r(x_0) \cap B^3_1$ for $r > 0$.

**Proof of Lemma 6.4** The strategy to show (6.22) is similar to lemma 6.3, that is to establish a modified boundary monotonicity inequality and a boundary energy decay property. More precisely, we first need

**Claim 8.** There exists $0 < \delta_0 \leq \frac{1}{2}$, depending only on $\partial B^3_1$, such that for any $x_0 \in \partial B^3_1$ and $0 < r \leq R \leq \delta_0$, it holds
\[
r^{-1} \int_{B^+_r(x_0)} |\nabla d|^2 \leq 8 R^{-1} \int_{B^+_R(x_0)} |\nabla d|^2 + 16 R \int_{B^+_R(x_0)} |\tau|^2.
\]

For $r > 0$, set $\mathbb{B}^+_r = B_r(0) \cap \{ x = (x_1, x_2, x_3) \in \mathbb{R}^3 : x_3 \geq 0 \}$, $T_r = \mathbb{B}^+_r \cap \{ x = (x_1, x_2, x_3) \in \mathbb{R}^3 : x_3 = 0 \}$, and $S^+_r = \partial \mathbb{B}^+_r \setminus T_r$. By the standard boundary flatten argument, there exists $\delta_0 > 0$ depending only on $\partial B^3_1$ such that for any $x_0 \in \partial B^3_1$ there exists a smooth diffeomorphism $\Phi_0 : \mathbb{B}^-_{\delta_0} \to B^+_1(x_0)$ such that $\Phi_0(0) = x_0$, $\Phi_0(T_{\delta_0}) = B^+_1(x_0) \cap \partial B^3_1$, and
\[
|\Phi_0(x) - x_0| \leq C |x|^2, \quad |\nabla \Phi_0(x) - \text{Id}| \leq C |x|, \quad |\nabla^2 \Phi_0(x)| \leq C, \quad \forall x \in \mathbb{B}^+_1,
\]
where $\text{Id}$ denotes the identity map in $\mathbb{R}^3$.

Set $g = \Phi_0^*(g_0)$ in $\mathbb{B}^-_{\delta_0}$, pull-back of the euclidean metric $g_0 = dx^2$ in $B^+_1(x_0)$. Consider $\tilde{d} = d \circ \Phi_0 : \mathbb{B}^+_{\delta_0} \to \mathbb{S}^2$. Then it is not hard to check that $\tilde{d} : (\mathbb{B}^{+}_{\delta_0}, g) \to \mathbb{S}^2$ is an approximated harmonic map, i.e.,
\[
\Delta_g \tilde{d} + |\nabla \tilde{d}|^2_g \tilde{d} = \tau(\tilde{d}) \quad \text{in} \quad \mathbb{B}^+_r; \quad \tilde{d} = e \quad \text{on} \quad T_{\delta_0},
\]
and
\[
|\tau(\tilde{d})|(x) \leq C |\tau(d)|(\Phi_0(x)), \quad \forall x \in \mathbb{B}^+_1,
\]
where $\Delta_g$ is the Laplace operator with respect to $g$, and $|\nabla \tilde{d}|^2_g$ is the Dirichlet energy density of $\tilde{d}$ with respect to $g$. Note that by (6.24), $g$ satisfies
\[
|g(x) - g_0| \leq C |x|^2, \quad |\nabla g(x)| \leq C |x|, \quad |\nabla^2 g(x)| \leq C, \quad \forall x \in \mathbb{B}^+_1.
\]

Based on (6.27), (6.25), and (6.26), we may for simplicity assume that $x_0 = 0$ and $d : (\mathbb{B}^+_{\delta_0}, g_0) \to \mathbb{S}^2$ is an approximated harmonic map with tension field $\tau(d)$. Since $d = e$ on $T_{\delta_0}$, it is easy to see
\[ x \cdot \nabla d = 0 \text{ on } T_{\delta_0}. \] For \( 0 < r \leq \delta_0 \), multiplying (6.10) by \( x \cdot \nabla d \) and integrating the resulting equation over \( \mathbb{B}_r^+ \), we get

\[
\frac{1}{2} \int_{\mathbb{B}_r^+} |\nabla d|^2 - \frac{r}{2} \int_{S^+_r} |\nabla d|^2 + r \int_{S^+_r} \left| \frac{\partial d}{\partial r} \right|^2 \frac{2}{r} = \int_{\mathbb{B}_r^+} \langle \tau(d), x \cdot \nabla d \rangle.
\]

This implies

\[
\frac{d}{dr} \left( r^{-1} \int_{\mathbb{B}_r^+} \left( \frac{1}{2} |\nabla d|^2 - \langle \tau(d), x \cdot \nabla d \rangle \right) \right) = r^{-1} \int_{S^+_r} \left| \frac{\partial d}{\partial r} \right|^2 - \int_{S^+_r} \langle \tau(d), \frac{\partial d}{\partial r} \rangle.
\]

(Integrating (6.28) over \( 0 < r < R \leq \delta_0 \) and applying Hölder’s inequality, we obtain

\[
r^{-1} \int_{\mathbb{B}_r^+} |\nabla d|^2 \leq 8R^{-1} \int_{\mathbb{B}_R^+} |\nabla d|^2 + 16R \int_{\mathbb{B}_R^+} |\tau(d)|^2.
\]

This gives (6.23).

Next we need

**Claim 9.** For any \( \alpha \in (0, \frac{1}{2}) \), there exists \( \theta_0 \in (0, \frac{1}{4}) \) such that for any \( x_0 \in \partial B^3 \) and \( 0 < r < \delta_0 \), it holds

\[
(\theta_0 r)^{-1} \int_{B^+_{\theta_0 r}(x_0)} |\nabla d|^2 \leq C \theta_0^2 r^{-1} \int_{B^+_{\theta_0 r}(x_0)} |\nabla d|^2 + C \theta_0 r \int_{B^+_{\theta_0 r}(x_0)} |\tau(d)|^2.
\]

For simplicity, we again assume \( x_0 = 0 \) and \( B^+_{\theta_0}(x_0) = \mathbb{B}^+_{\theta_0} \). The proof is similar to [9] lemma 3.3, and we only sketch it. To obtain (6.29), we perform suitable extensions of \( d \) to \( \mathbb{B}_{\delta_0} \) as follows. Let \( \tilde{d} : \mathbb{B}_{\delta_0} \to \mathbb{R}^3 \) be the extension of \( d \) that is even with respect to \( x_3 \), and let \( \tau : \mathbb{B}_{\delta_0} \to \mathbb{R}^3 \) be the extension of \( \tau(d) \) that is odd with respect to \( x_3 \). Define \( w : \mathbb{B}_{\delta_0} \to \mathbb{R}^3 \) by

\[
w(x) = \begin{cases} (d - e)(x) & \text{if } x = (x_1, x_2, x_3) \in \mathbb{B}_{\delta_0} \text{ and } x_3 \geq 0, \\ -(d - e)(x_1, x_2, -x_3) & \text{if } x = (x_1, x_2, x_3) \in \mathbb{B}_{\delta_0} \text{ and } x_3 < 0. \end{cases}
\]

For \( 0 < r \leq \delta_0 \), let \( \eta \in C_0^\infty(\mathbb{R}^3) \) be even with respect to \( x_3 \), \( 0 \leq \eta \leq 1 \), \( \eta = 1 \) in \( \mathbb{B}_r \), \( \eta = 0 \) outside \( \mathbb{B}_r \), and \( |\nabla \eta| \leq Cr^{-1} \). To proceed with the proof, we need

\[
\nabla \cdot (\nabla w \times \tilde{d}) = \tilde{\tau} \times \tilde{d} \quad \text{in} \quad \mathcal{D}'(\mathbb{B}_{\delta_0}).
\]

To see (6.31), let \( \phi \in C_0^\infty(\mathbb{B}_{\delta_0}) \) and write \( \phi = \phi_o + \phi_\circ \), here \( \phi_o \) \( (\phi_\circ) \) is even \( (\text{odd}) \) with respect to \( x_3 \) respectively. Then (6.31) follows from

\[
\int_{\mathbb{B}_{\delta_0}} \nabla w \times \tilde{d} \cdot \nabla \phi = 2 \int_{\mathbb{B}_{\delta_0}^+} \nabla w \times \tilde{d} \cdot \nabla \phi_o = -2 \int_{\mathbb{B}_{\delta_0}^+} \nabla \cdot (\nabla d \times d) \cdot \phi_o
\]

\[
= -2 \int_{\mathbb{B}_{\delta_0}^+} \tau(d) \times d \cdot \phi_o = -\int_{\mathbb{B}_{\delta_0}^+} \tilde{\tau} \times \tilde{d} \cdot \phi.
\]

It follows from (6.30) and (6.23) that \( \nabla w \in M^{2,2}(\mathbb{B}_{\delta_0}) \), and

\[
\|\nabla w\|_{M^{2,2}(\mathbb{B}_{\delta_0})} \leq C \epsilon.
\]

From (6.31), it is easy to check that \( \nabla \cdot (\eta^2 \nabla w \times \tilde{d}) \in L^2(\mathbb{R}^3) \), and

\[
\|\nabla \cdot (\eta^2 \nabla w \times \tilde{d})\|_{L^2(\mathbb{R}^3)} \leq C \left( r^{-1} \|\nabla d\|_{L^2(\mathbb{B}_r^+)} + \|\tau(d)\|_{L^2(\mathbb{B}_r^+)} \right).
\]
Observe that
\[
2 \int_{\mathbb{B}_r^+} |\nabla d|^2 \leq 2 \int_{\mathbb{R}^3} \eta^2 |\nabla w \times d|^2 = \int_{\mathbb{R}^3} \eta^2 |\nabla w \times \tilde{d}|^2
\]
\[
= - \int_{\mathbb{R}^3} \nabla (\eta^2 \nabla w \times \tilde{d}) \cdot (w \times \tilde{d}) + \int_{\mathbb{R}^3} \eta^2 [\nabla w \times \tilde{d} - \lambda] \cdot w + \lambda \int_{\mathbb{R}^3} \eta^2 w
\]
\[= I + II + III,
\]
where
\[
\lambda = \frac{\int_{\mathbb{R}^3} \eta^2 (\nabla w \times \tilde{d}) \times \nabla \tilde{d}}{\int_{\mathbb{R}^3} \eta^2}.
\]
By the Poincaré inequality, we have
\[
|III| \leq |\lambda| \int_{\mathbb{B}_r^+} |w| \leq C(r^{-1} \int_{\mathbb{B}_r^+} |\nabla d|^2)^{\frac{1}{2}} \int_{\mathbb{B}_r^+} |\nabla d|^2.
\]
Applying (6.33), I can be estimated by
\[
|I| \leq \left\| \nabla \cdot (\eta^2 \nabla w \times \tilde{d}) \right\|_{L^2(\mathbb{R}^3)} \left\| w \right\|_{L^2(\mathbb{B}_r^+)}
\]
\[\leq C \left( r^{-1} \left\| \nabla d \right\|_{L^2(\mathbb{B}_r^+)} + \left\| \tau (d) \right\|_{L^2(\mathbb{B}_r^+)} \right) \left\| d - e \right\|_{L^2(\mathbb{B}_r^+)}
\]
\[\leq \gamma \left( \left\| \nabla d \right\|^2_{L^2(\mathbb{B}_r^+)} + r^2 \left\| \tau (d) \right\|^2_{L^2(\mathbb{B}_r^+)} \right) + C \gamma^{-1} r^{-2} \int_{\mathbb{B}_r^+} |d - e|^2
\]
for any $\gamma \in (0, 1)$. Let $\tilde{w} : \mathbb{R}^3 \to \mathbb{R}^3$ be an extension of $w$ such that
\[
\left\| \nabla \tilde{w} \right\|_{M^{2,2}(\mathbb{R}^3)} \leq C \left\| \nabla w \right\|_{M^{2,2}(\mathbb{B}_{\delta_0})}.
\]
Then, from (6.32) and the Poincaré inequality, we have
\[
[w]_{\text{BMO}(\mathbb{R}^3)} \leq C \left\| \nabla \tilde{w} \right\|_{M^{2,2}(\mathbb{R}^3)} \leq C \left\| \nabla w \right\|_{M^{2,2}(\mathbb{B}_{\delta_0})} \leq C \sqrt{\epsilon}.
\]
(6.34)
We use the duality between $H^1(\mathbb{R}^3)$ and BMO(\mathbb{R}^3), similar to [9] lemma 3.3 and lemma 2.6, to estimate II by
\[
|II| \leq C \left\| \eta^2 (\nabla w \times \tilde{d}) \times \nabla \tilde{d} - \lambda \right\|_{H^1(\mathbb{R}^3)} [\tilde{w}]_{\text{BMO}(\mathbb{R}^3)}
\]
\[\leq C \left[ \left\| \nabla d \right\|^2_{L^2(\mathbb{B}_r^+)} + r^2 \left\| \nabla \cdot (\nabla d \times d) \right\|_{L^2(\mathbb{B}_r^+)} \right] \left\| \nabla w \right\|_{M^{2,2}(\mathbb{B}_{\delta_0})}
\]
\[\leq C \sqrt{\epsilon} \left[ \left\| \nabla d \right\|^2_{L^2(\mathbb{B}_r^+)} + r^2 \left\| \tau (d) \right\|^2_{L^2(\mathbb{B}_r^+)} \right].
\]
Putting these estimates together, we obtain
\[
\frac{1}{r^2 / 2} \int_{\mathbb{B}_r / 2} |\nabla d|^2 \leq C \sqrt{\epsilon} + \gamma \left[ \frac{1}{r} \int_{\mathbb{B}_r} |\nabla d|^2 + r \int_{\mathbb{B}_r} |\tau (d)|^2 \right] + C \gamma^{-1} \frac{1}{r^3} \int_{\mathbb{B}_r} |d - e|^2.
\]
(6.35)
To deduce (6.29) from (6.35), we need
\textbf{Claim 10}. There exists $\theta_0 = \theta_0(\epsilon)$ such that for $0 < r < \delta_0$,
\[
\frac{1}{(\theta_0 r)^2} \int_{\mathbb{B}_{\delta_0}/r} |d - e|^2 \leq C \theta_0^2 \frac{1}{r} \int_{\mathbb{B}_r} |\nabla d|^2.
\]
(6.36)
We prove (6.36) by contradiction. Suppose that it were false. Then for any \( \theta \in (0,1) \), there exist \( \epsilon_k \to 0 \), \( 0 < r_k < \delta_0 \), \( e_k \in \mathbb{S}^2 \), and \( d_k \in C^\infty(\mathbb{B}_{\theta_0}^+, \mathbb{S}^2) \) such that \( d_k = e_k \) on \( T_{\theta_0} \),

\[
    r_k^{-1} \int_{\mathbb{B}_{r_k}^+} |\nabla d_k|^2 = \epsilon_k^2 \quad \text{and} \quad r_k \int_{\mathbb{B}_{r_k}^+} |\tau(d_k)|^2 \leq \epsilon_k^2,
\]

but

\[
    \frac{1}{(\theta r_k)^3} \int_{\mathbb{B}_{\theta r_k}^+} |d_k - e_k|^2 > k\theta^2 \frac{1}{r_k} \int_{\mathbb{B}_{r_k}^+} |\nabla d_k|^2.
\]

Define \( \tilde{d}_k(x) = \frac{d_k(r_k x) - e_k}{\epsilon_k} : \mathbb{B}_1^+ \to \mathbb{S}^2 \). Then we have

\[
    \tilde{d}_k|_{T_1} = 0, \quad \int_{\mathbb{B}_1^+} |\nabla \tilde{d}_k|^2 = 1,
\]

and

\[
    \Delta \tilde{d}_k = f_k := -\epsilon_k|\nabla \tilde{d}_k|^2 d_k + \epsilon_k^{-1} \tau(d_k) \to 0 \text{ in } L^2(\mathbb{B}_1^+),
\]

but

\[
    \frac{1}{\theta^3} \int_{\mathbb{B}_{\theta}^+} |\tilde{d}_k|^2 > k\theta^2.
\]

From (6.39), \( \{\tilde{d}_k\} \subset H^1(\mathbb{B}_1^+, \mathbb{R}^3) \) is bounded. We may assume that \( \tilde{d}_k \to \tilde{d} \) weakly in \( H^1(\mathbb{B}_1^+) \), strongly in \( L^2(\mathbb{B}_1^+) \). It follows from (6.39) and (6.40) that

\[
    \tilde{d}|_{T_1} = 0, \quad \int_{\mathbb{B}_1^+} |\nabla \tilde{d}|^2 \leq 1,
\]

and

\[
    \Delta \tilde{d} = 0 \text{ in } \mathbb{B}_1^+.
\]

By the standard theory of harmonic functions, we have that for any \( \theta \in (0,1) \),

\[
    \frac{1}{\theta^3} \int_{\mathbb{B}_{\theta}^+} |\tilde{d}|^2 \leq C\theta^2.
\]

Since \( \tilde{d}_k \to \tilde{d} \) in \( L^2(\mathbb{B}_1^+) \), (6.44) contradicts to (6.41). Hence Claim 10 is proven.

Putting (6.36) into (6.35), we can obtain that

\[
    \frac{1}{\theta_0 r} \int_{\mathbb{B}_{\theta_0 r}^+} |\nabla d|^2 \leq C(\sqrt{\epsilon} + \gamma) \left[ \frac{1}{2\theta_0 r} \int_{\mathbb{B}_{2\theta_0 r}^+} |\nabla d|^2 + \theta_0 r \int_{\mathbb{B}_{2\theta_0 r}^+} |\tau(d)|^2 \right] + C\gamma^{-1} \theta_0^2 \frac{1}{r^3} \int_{\mathbb{B}_r^+} |\nabla d|^2
\]

\[
    \leq C[(\sqrt{\epsilon} + \gamma)\theta_0^{-1} + \gamma^{-1} \theta_0^2] \frac{1}{r^3} \int_{\mathbb{B}_r^+} |\nabla d|^2 + C\theta_0 r \int_{\mathbb{B}_r^+} |\tau(d)|^2
\]

\[
    \leq C\theta_0^{2\alpha} \frac{1}{r^3} \int_{\mathbb{B}_r^+} |\nabla d|^2 + C\theta_0 r \int_{\mathbb{B}_r^+} |\tau(d)|^2,
\]

for any \( 0 < \alpha < \frac{1}{2} \), provided we choose \( \gamma = \theta_0^{2-2\alpha} \) and \( \epsilon \leq \theta_0^{2+4\alpha} \). Hence (6.29) is proven.
It is standard that iterations of (6.29) imply that for any \( \alpha \in (0, \frac{1}{2}) \),
\[
\frac{1}{s} \int_{B_s^+(x_0)} |\nabla d|^2 \leq C \left( \frac{s}{r} \right)^{2\alpha} \int_{B_r^+(x_0)} |\nabla d|^2 + C s \int_{B_r^+(x_0)} |\tau(d)|^2
\]
(6.46)
holds for any \( x_0 \in \partial B_3 \) and \( 0 < s < r < \delta_0 \). Combining (6.46) with (6.21), we can obtain that for any \( 0 < \alpha < \frac{1}{2} \),
\[
\frac{1}{s} \int_{B_s(x_0) \cap B_3^+} |\nabla d|^2 \leq C \left( \frac{s}{r} \right)^{2\alpha} \int_{B_r(x_0) \cap B_3^+} |\nabla d|^2 + C s \int_{B_r(x_0) \cap B_3^+} |\tau(d)|^2
\]
(6.47)
holds for any \( x_0 \in \overline{B_3} \) and \( 0 < s < r < \delta_0 \). This, combined with Morrey’s decay lemma (see [36]) implies that for any \( \alpha \in (0, \frac{1}{2}) \),
\[
[d]_{C^{\alpha}(\overline{B_3})} \leq C \left[ \|\nabla d\|_{L^2(B_3)} + \|\tau(d)\|_{L^2(\overline{B_3})} \right].
\]
(6.48)
It is well known that we can use the equation (6.25) to improve the estimate (6.48) to the case that \( \alpha = \frac{1}{2} \). Hence lemma 6.4 is proven. This completes the proof of Theorem 6.2. Thus Theorem 1.3 is proven.
