SOBOLEV SPACES ON GRADED GROUPS

VÉRONIQUE FISCHER AND MICHAEL RUZHANSKY

Abstract. We study the $L^p$-properties of positive Rockland operators and define Sobolev spaces on general graded groups. This generalises the case of sub-Laplacians on stratified groups studied by G. Folland in [3]. We show that the defined Sobolev spaces are actually independent of the choice of a positive Rockland operator. Furthermore, we show that they are interpolation spaces and establish duality and Sobolev embedding theorems in this context.

1. Introduction

One can define Sobolev spaces on $\mathbb{R}^n$ in various equivalent ways (see e.g. [15]), for example using the Euclidean Fourier transform on $\mathbb{R}^n$ or the properties of the Laplace operator. This can also be done on compact Lie groups (see e.g. [18], [19], also for the corresponding global theory of pseudo-differential operators). Replacing the Laplace operator with a (left-invariant) sub-Laplacian on a stratified nilpotent Lie group and using the associated heat semigroup, Folland showed in [3] that the corresponding spaces are different from their Euclidean (abelian) counterpart but share many properties with them. See also [20]. Using Littlewood-Payley decompositions, this was generalised in [5] to the context of Lie groups of polynomial growth, which in general do not have a (global) homogeneous structure.

Our purpose here is to define functional spaces of Sobolev type on graded (homogeneous) Lie groups. This class of groups has proved to be a natural setting to generalise several questions of the Euclidean harmonic analysis and contains many interesting examples: the abelian Euclidean case of $\mathbb{R}^n$, the Heisenberg group with its natural structure as a stratified group, and more generally any stratified group, but also for example the Heisenberg group with a different graded non-stratified structure (see, e.g., $\mathbb{H}_1$ in Section 5.3). These groups appear naturally in the geometry of certain symmetric domains and in some sub-elliptic partial differential equations. In fact, one can argue easily that the analysis on stratified groups such as in [3] was born out of studying operators based on sums of squares of vector fields on certain manifolds, nowadays called Heisenberg manifolds. Similarly, our present analysis should help understanding the case of more general operators, of higher degrees as differential operators and in terms of homogeneity.

Key words and phrases. Harmonic analysis on nilpotent Lie groups, Sobolev spaces, graded groups, Rockland operators, heat semigroup.
In this paper, we define functional spaces on graded groups and show some important properties such as interpolation, duality, adapted Sobolev embeddings and so on. Hence this justifies our choice of calling these functional spaces Sobolev spaces. Our construction uses positive Rockland operators instead of sub-Laplacians as the latter are no longer always homogeneous. Although our analysis is closely related to Folland’s [3], one important obstacle is the fact that positive Rockland operators may be of high degree, and not only 2 as in the case of sub-Laplacians. This has deep implications. For example, a Rockland operator may not have a unique homogeneous fundamental solution. Also, the powerful Hunt theorem [13] is no longer available for operators of order larger than 2.

Naturally, when we consider a graded group which is stratified, we recover the Sobolev spaces defined by Folland in [3] which then coincide with the Sobolev spaces obtained in [5] on any Lie group of polynomial growth. However, for a general graded (non-stratified) group, our Sobolev spaces may differ from the ones in [5], see Section 5.3 in this paper. They will also be slightly different from the Goodman-Sobolev spaces defined by Goodman on graded Lie groups for integer exponents only in [10, Sec. III. 5.4], see again Section 5.3.

The advantage of the Sobolev spaces defined in this paper is a collection of natural functional analytic properties making them useful in applications: for example, Goodman’s versions [10] are not interpolation spaces while our spaces are. Moreover our Sobolev are adapted to the homogeneous structure (we could in fact also define homogeneous Sobolev spaces, see our last remark in Section 5.3). For instance, homogeneous left-invariant differential operators maps Sobolev spaces to other Sobolev spaces with ‘a loss of derivatives’ corresponding to the homogeneous degree. This is not true in general with [5].

For the sake of completeness, our analysis includes the definition and some properties for the case $p = \infty$. This is new already for the stratified case, although this could have been done by adapting Folland’s methods.

This paper is organised as follows. After some preliminaries about graded groups and their homogeneous structure in Section 2 we first define the fractional powers of a positive Rockland operator in Section 3 as well as its Riesz and Bessel potentials. This enables us to define our Sobolev spaces in Section 4, where we also show that they satisfy the properties expected from Sobolev spaces, e.g. interpolation and duality amongst others. In the last section, we show a ‘Sobolev’ embedding theorem and we also compare our Sobolev spaces with other known spaces.

2. Preliminaries

In this section, after defining graded Lie groups, we recall their homogeneous structure as well as the definition and some properties of their Rockland operators.
2.1. Graded and homogeneous groups. Here we recall briefly the definition of graded nilpotent Lie groups and their natural homogeneous structure. A complete description of the notions of graded and homogeneous nilpotent Lie groups may be found in [4, ch1].

We will be concerned with graded Lie groups $G$ which means that $G$ is a connected and simply connected Lie group whose Lie algebra $\mathfrak{g}$ admits an $N$-gradation $\mathfrak{g} = \oplus_{\ell=1}^{\infty} \mathfrak{g}_{\ell}$ where the $\mathfrak{g}_{\ell}$, $\ell = 1, 2, \ldots$, are vector subspaces of $\mathfrak{g}$, all but finitely many equal to $\{0\}$, and satisfying $[\mathfrak{g}_{\ell}, \mathfrak{g}_{\ell'}] \subset \mathfrak{g}_{\ell+\ell'}$ for any $\ell, \ell' \in \mathbb{N}$. This implies that the group $G$ is nilpotent. Examples of such groups are the Heisenberg group and, more generally, all stratified groups (which by definition correspond to the case $\mathfrak{g}_{1}$ generating the full Lie algebra $\mathfrak{g}$).

We construct a basis $X_{1}, \ldots, X_{n}$ of $\mathfrak{g}$ adapted to the gradation, by choosing a basis $\{X_{1}, \ldots, X_{n}\}$ of $\mathfrak{g}_{1}$ (this basis is possibly reduced to $\{0\}$), then $\{X_{n_{1}+1}, \ldots, X_{n_{1}+n_{2}}\}$ a basis of $\mathfrak{g}_{2}$ (possibly $\{0\}$ as well as the others) and so on. Via the exponential mapping $\exp_{G} : \mathfrak{g} \rightarrow G$, we identify the points $(x_{1}, \ldots, x_{n}) \in \mathbb{R}^{n}$ with the points $x = \exp_{G}(x_{1}X_{1} + \cdots + x_{n}X_{n})$ in $G$. Consequently we allow ourselves to denote by $C(G)$, $D(G)$ and $S(G)$ etc, the spaces of continuous functions, of smooth and compactly supported functions or of Schwartz functions on $G$ identified with $\mathbb{R}^{n}$, and similarly for distributions with the duality notation $\langle \cdot, \cdot \rangle$.

This basis also leads to a corresponding Lebesgue measure on $\mathfrak{g}$ and the Haar measure $dx$ on the group $G$, hence $L^{p}(G) \cong L^{p}(\mathbb{R}^{n})$. The group convolution of two functions $f$ and $g$, for instance integrable, is defined via

$$(f \ast g)(x) := \int_{G} f(y)g(y^{-1}x)dy.$$ 

The convolution is not commutative: in general, $f \ast g \neq g \ast f$. However, apart from the lack of commutativity, group convolution and the usual convolution on $\mathbb{R}^{n}$ share many properties. For example, we have

$$(f \ast g, h) = (f, h \ast \tilde{g}), \quad \text{with} \quad \tilde{g}(x) = g(x^{-1}).$$

And the Young convolutions inequalities hold: if $f_{1} \in L^{p}(G)$ and $f_{2} \in L^{q}(G)$ with $1 \leq p, q, r \leq \infty$ and $\frac{1}{p} + \frac{1}{q} = \frac{1}{r} + 1$, then $f_{1} \ast f_{2} \in L^{r}(G)$ and

$$\|f_{1} \ast f_{2}\|_{r} \leq \|f_{1}\|_{p}\|f_{2}\|_{q}.\tag{2.1}$$

The coordinate function $x = (x_{1}, \ldots, x_{n}) \in G \mapsto x_{j} \in \mathbb{R}$ is denoted by $x_{j}$. More generally we define for every multi-index $\alpha \in \mathbb{N}_{0}^{n}$, $x^{\alpha} := x_{1}^{\alpha_{1}}x_{2}^{\alpha_{2}}\cdots x_{n}^{\alpha_{n}}$, as a function on $G$. Similarly we set $X^{\alpha} = X_{1}^{\alpha_{1}}X_{2}^{\alpha_{2}}\cdots X_{n}^{\alpha_{n}}$ in the universal enveloping Lie algebra $U(\mathfrak{g})$ of $\mathfrak{g}$.

For any $r > 0$, we define the linear mapping $D_{r} : \mathfrak{g} \rightarrow \mathfrak{g}$ by $D_{r}X = r^{\ell}X$ for every $X \in \mathfrak{g}_{\ell}$, $\ell \in \mathbb{N}$. Then the Lie algebra $\mathfrak{g}$ is endowed with the family of dilations $\{D_{r}, r > 0\}$ and becomes a homogeneous Lie algebra in the sense of [4]. We re-write the set of integers $\ell \in \mathbb{N}$ such that $\mathfrak{g}_{\ell} \neq \{0\}$ into the increasing sequence of positive integers $v_{1}, \ldots, v_{n}$ counted with multiplicity, the multiplicity of $\mathfrak{g}_{\ell}$ being its dimension. In this way, the integers $v_{1}, \ldots, v_{n}$
become the weights of the dilations and we have 
\[ D_r X_j = r^{\nu_j} X_j, \quad j = 1, \ldots, n, \]
on the chosen basis of \( g \). The associated group dilations are defined by
\[
D_r (x) = r \cdot x := (r^{\nu_1} x_1, r^{\nu_2} x_2, \ldots, r^{\nu_n} x_n), \quad x = (x_1, \ldots, x_n) \in G, \ r > 0.
\]
In a canonical way this leads to the notions of homogeneity for functions and operators. For instance the degree of homogeneity of \( x^\alpha \) and \( X^\alpha \), viewed respectively as a function and a differential operator on \( G \), is \( [\alpha] = \sum_j \nu_j \alpha_j \). Indeed, let us recall that a vector of \( g \) defines a left-invariant vector field on \( G \) and, more generally, that the universal enveloping Lie algebra of \( g \) is isomorphic with the left-invariant differential operators; we keep the same notation for the vectors and the corresponding operators.

Recall that a homogeneous pseudo-norm on \( G \) is a continuous function \(| \cdot | : G \to [0, +\infty) \) homogeneous of degree 1 on \( G \) which vanishes only at 0. This often replaces the Euclidean pseudo-norm in the analysis on homogeneous Lie groups:

**Proposition 2.1.**

1. Any homogeneous pseudo-norm \(| \cdot | \) on \( G \) satisfies a triangle inequality up to a constant:
   \[
   \exists C \geq 1 \quad \forall x, y \in G \quad |xy| \leq C(|x| + |y|).
   \]
   It partially satisfies the reverse triangle inequality:
   \[
   \forall b \in (0,1) \quad \exists C = C_b \geq 1 \quad \forall x, y \in G \quad |y| \leq b|x| \implies |xy| - |x| \leq C|y|.
   \]

2. Any two homogeneous pseudo-norms \(| \cdot |_1 \) and \(| \cdot |_2 \) are equivalent in the sense that
   \[
   \exists C > 0 \quad \forall x \in G \quad C^{-1} |x|_2 \leq |x|_1 \leq C|x|_2.
   \]

3. A concrete example of a homogeneous pseudo-norm is given via
   \[
   |x|_{\nu_0} := \left( \sum_{j=1}^n x_j^{2\nu_0/\nu_j} \right)^{1/2\nu_0},
   \]
   with \( \nu_0 \) a common multiple to the weights \( \nu_1, \ldots, \nu_n \).

Various aspects of analysis on \( G \) can be developed in a comparable way with the Euclidean setting, see [1], sometimes replacing the topological dimension
\[
n := \dim G = \sum_{\ell=1}^\infty \dim g_\ell
\]
of the group \( G \) by its homogeneous dimension
\[
Q := \sum_{\ell=1}^\infty \ell \dim g_\ell = \nu_1 + \nu_2 + \ldots + \nu_n.
\]

For example, there is an analogue of polar coordinates on homogeneous groups with \( Q \) replacing \( n \):
Proposition 2.2. Let $|·|$ be a fixed homogeneous pseudo-norm on $G$. Then there is a (unique) positive Borel measure $\sigma$ on the unit sphere $S := \{x \in G : |x| = 1\}$, such that for all $f \in L^1(G)$, we have

$$\int_G f(x)dx = \int_0^\infty \int_S f(ry)r^{Q-1}d\sigma(y)dr.$$  

Another example is the following property regarding kernels or operators of type $\nu$ (see [3] and [4, Chapter 6 A]):

Definition 2.3. A distribution $\kappa \in D'(G)$ which is smooth away from the origin and homogeneous of degree $\nu - Q$ is called a kernel of type $\nu \in \mathbb{C}$ on $G$. The corresponding convolution operator $f \in D(G) \mapsto f * \kappa$ is called an operator of type $\nu$.

Theorem 2.4. An operator of type $\nu$ with $\nu \in [0, Q)$ is $(-\nu)$-homogeneous and extends to a bounded operator from $L^p(G)$ to $L^q(G)$ whenever $p, q \in (1, \infty)$ satisfy $\frac{1}{p} - \frac{1}{q} = \frac{\text{Re}\nu}{Q}$.

Exactly as in the Euclidean setting, in the case $\text{Re}\nu \in (0, Q)$, any smooth function away from the origin which is $(\nu - Q)$-homogeneous defines a distribution. However in the case $\text{Re}\nu = 0$, one needs to add a condition to guarantee the same property:

Proposition 2.5. Let $\kappa$ be a smooth function away from the origin homogeneous of degree $\nu$ with $\text{Re}\nu = -Q$. It coincides with the restriction to $G \setminus \{0\}$ of a distribution in $D'(G)$ if and only if its mean value is zero, that is, when $\int_S \kappa d\sigma = 0$ where $\sigma$ is the measure on the unit sphere $S$ of a homogeneous pseudo-norm given by the polar change of coordinates, see Proposition 2.2. This condition is independent of the choice of a homogeneous pseudo-norm.

The problems about (group) convolving distributions on $G$ are essentially the same as in the case of the abelian convolution on $\mathbb{R}^n$. The convolution $\tau_1 * \tau_2$ of two distributions $\tau_1, \tau_2 \in D'(G)$ is well defined as a distribution provided that at most one of them has compact support. However, additional assumptions must be imposed in order to define convolutions of distributions with non-compact supports. Furthermore, the associativity of the group convolution product law

$$\tau_1 * \tau_2 * \tau_3 = \tau_1 * (\tau_2 * \tau_3),$$

holds when at most one of the $\tau_j$’s has non-compact support but not necessarily when only one of the $\tau_j$’s has compact support even if each convolution in (2.5) could have a meaning.

The following proposition establishes that there is no such pathology appearing when considering convolution with kernel of type $\nu$ with $\text{Re}\nu \in [0, Q)$. This will be useful in the sequel.

Proposition 2.6. Let $G$ be a homogeneous group.
(i) Suppose $\nu \in \mathbb{C}$ with $0 \leq \Re \nu < Q$, $p \geq 1$, $q > 1$, and $r \geq 1$ given by $\frac{1}{r} = \frac{1}{p} + \frac{1}{q} - \frac{\Re \nu}{Q} - 1$. If $\kappa$ is a kernel of type $\nu$, $f \in L^p(G)$, and $g \in L^q(G)$, then $f \ast (g \ast \kappa)$ and $(f \ast g) \ast \kappa$ are well defined as elements of $L^r(G)$, and they are equal.

(ii) Suppose $\kappa_1$ is a kernel of type $\nu_1 \in \mathbb{C}$ with $\Re \nu_1 > 0$ and $\kappa_2$ is a kernel of type $\nu_2 \in \mathbb{C}$ with $\Re \nu_2 \geq 0$. We assume $\Re (\nu_1 + \nu_2) < Q$. Then $\kappa_1 \ast \kappa_2$ is well defined as a kernel of type $\nu_1 + \nu_2$. Moreover if $f \in L^p(G)$ where $1 < p < Q/(\Re (\nu_1 + \nu_2))$ then $(f \ast \kappa_1) \ast \kappa_2$ and $f \ast (\kappa_1 \ast \kappa_2)$ belong to $L^q(G)$, $\frac{1}{q} = \frac{1}{p} - \frac{\Re (\nu_1 + \nu_2)}{Q}$, and they are equal.

The approximations of the identity may be constructed on $G$ as on their Euclidean counterpart, replacing the topological dimension and the abelian convolution with the homogeneous dimension and the group convolution:

**Lemma 2.7.** Let $\phi \in L^1(G)$. Then the functions $\phi_t$, $t > 0$, defined via $\phi_t(x) = t^{-Q} \phi(t^{-1}x)$, are integrable and $\int \phi_t = \int \phi$ is independent of $t$. Furthermore, for any $f$ in $L^p(G)$, $C_0(G)$, $S(G)$ or $S'(G)$, the sequence of functions $f \ast \phi_t$ and $\phi_t \ast f$, $t > 0$, converges towards $(\int \phi) f$ as $t \to 0$ in $L^p(G)$, $C_0(G)$, $S(G)$ and $S'(G)$ respectively.

In Lemma 2.7, and in the whole paper, $C_0(G)$ denotes the space of continuous functions on $G$ which vanish at infinity. This means that $f \in C_0(G)$ when for every $\epsilon > 0$ there exists a compact set $K$ outside which we have $|f| < \epsilon$. Endowed with the supremum norm $\| \cdot \|_{\infty} = \| \cdot \|_{L^\infty(G)}$, it is a Banach space.

Recall that $\mathcal{D}(G)$, the space of smooth and compactly supported functions, is dense in $L^p(G)$ for $p \in [1, \infty)$ and in $C_0(G)$ (in which case we set $p = \infty$).

In Theorem 2.9, we will see that the heat semi-group associated to a positive Rockland operator gives an approximation of the identity which is commutative.

### 2.2. Rockland operators.

Here we recall the definition of Rockland operators and their main properties.

The definition of a Rockland operator uses the representations of the group. Here we consider only continuous unitary representations of $G$. We will often denote by $\pi$ such a representation, by $\mathcal{H}_\pi$ its Hilbert space and by $\mathcal{H}_\pi^\infty$ the subspace of smooth vectors. The corresponding infinitesimal representation on the Lie algebra $\mathfrak{g}$ and its extension to the universal enveloping Lie algebra $\mathfrak{u}(\mathfrak{g})$ are also denoted by $\pi$. We recall that $\mathfrak{g}$ and $\mathfrak{u}(\mathfrak{g})$ are identified with the spaces of left-invariant vector fields and of left-invariant differential operators on $G$ respectively.

**Definition 2.8.** A Rockland operator $\mathcal{R}$ on $G$ is a left-invariant differential operator $T$ which is homogeneous of positive degree and satisfies the Rockland condition:

(R) for each unitary irreducible representation $\pi$ on $G$, except for the trivial representation, the operator $\pi(T)$ is injective on $\mathcal{H}_\pi^\infty$, that is,

$$\forall v \in \mathcal{H}_\pi^\infty \quad \pi(T)v = 0 \implies v = 0.$$
Although the definition of a Rockland operator would make sense on a homogeneous Lie group (in the sense of [4]), it turns out (see [16], see also [2, Lemma 2.2]) that the existence of a (differential) Rockland operator on a homogeneous group implies that the homogeneous group may be assumed to be graded. This explains why we have chosen to restrict our presentation to graded Lie groups.

Some authors may have different conventions than ours regarding Rockland operators: for instance some choose to consider right-invariant operators and some definitions of a Rockland operator involve only the principal part of the operator. The analysis however would be exactly the same. In a different direction, Glowacki studied non-differentiable ($L^2$-bounded) operators which satisfy the Rockland condition in [8, 9].

In 1977, Rockland conjectured in [17] that the property in (R) which nowadays bears his name is equivalent to the hypoellipticity of the operator. This was eventually proved by Helffer and Nourrigat in [11]. Hence Rockland operators may be viewed as an analogue of elliptic operators (with a high degree of homogeneity) in a non-abelian subelliptic context. In the stratified case, one can check easily that any (left-invariant negative) sub-Laplacian,

\[ L = \sum_{j=1}^{n} Z_j^2 \quad \text{with } Z_1, \ldots, Z_n \text{ forming any basis of the first stratum } g_1, \]

is a Rockland operator. More generally it is not difficult to see that the operator

\[ \sum_{j=1}^{n} (-1)^{\frac{\nu_0}{\nu_j}} c_j X_j^{2 \frac{\nu_0}{\nu_j}} \quad \text{with } c_j > 0, \]

is a Rockland operator of homogeneous degree $2\nu_0$ if $\nu_0$ is any common multiple of $\nu_1, \ldots, \nu_n$. Hence Rockland operators do exist on any graded Lie group (not necessarily stratified). Furthermore, if $\mathcal{R}$ is a Rockland operator, then one can show easily that its powers $\mathcal{R}^k$, $k \in \mathbb{N}$, and its complex conjugate $\overline{\mathcal{R}}$ are also Rockland operators.

If a Rockland operator $\mathcal{R}$ which is formally self-adjoint, that is, $\mathcal{R}^* = \mathcal{R}$ as elements of the universal enveloping algebra $U(\mathfrak{g})$, is fixed, then it admits a self-adjoint extension on $L^2(G)$ [4, p.131]. In this case we will denote by $\mathcal{R}_2$ the self-adjoint extension and by $E$ its spectral measure:

\[ \mathcal{R}_2 = \int_{\mathbb{R}} \lambda dE(\lambda). \]

2.3. Positive Rockland operators and their heat kernels. In this section we summarise properties of positive Rockland operators that are important for our analysis.

Recall that an operator $T$ on a Hilbert space $\mathcal{H}$ is positive when for any vectors $v, v_1, v_2 \in \mathcal{H}$ in the domain of $T$, we have $(T(v_1, v_2)) = (v_1, Tv_2)_{\mathcal{H}}$ and $(Tv, v)_{\mathcal{H}} \geq 0$. If $T$ is a left-invariant differential operator acting on $G$, then $T$ is positive when $T$ is formally self-adjoint, that is,
$T^* = T$ in $\mathfrak{U}(\mathfrak{g})$, and satisfies

$$\forall f \in \mathcal{D}(G) \quad \int_G Tf(x)\overline{f(x)}\,dx \geq 0.$$ 

Note that if $G$ is stratified and $\mathcal{L}$ is a (left-invariant negative) sub-Laplacian, then $-\mathcal{L}$ is a positive Rockland operator. The example in (2.7) is also a positive Rockland operator. Hence positive Rockland operators always exist on any graded Lie group. Moreover if $\mathcal{R}$ is a positive Rockland operator, then its powers $\mathcal{R}^k$, $k \in \mathbb{N}$, and its complex conjugate $\overline{\mathcal{R}}$ are also positive Rockland operators.

Let us fix a positive Rockland operator $\mathcal{R}$ on $G$. By functional calculus (see (2.8)), we can define the spectral multipliers

$$e^{-t\mathcal{R}^2} := \int_0^\infty e^{-t\lambda}dE(\lambda), \quad t > 0,$$

which form the heat semigroup of $\mathcal{R}$. The operators $e^{-t\mathcal{R}^2}$ are invariant under left-translations and are bounded on $L^2(G)$. Therefore the Schwartz kernel theorem implies that each operator $e^{-t\mathcal{R}^2}$ admits a unique distribution $h_t \in \mathcal{S}'(G)$ as its convolution kernel:

$$e^{-t\mathcal{R}^2}f = f * h_t, \quad t > 0, \ f \in \mathcal{S}(G).$$

The distributions $h_t, t > 0$, are called the heat kernels of $\mathcal{R}$. We summarise their main properties in the following theorem:

**Theorem 2.9.** Let $\mathcal{R}$ be a positive Rockland operator on $G$ which is homogeneous of degree $\nu \in \mathbb{N}$. Then each distribution $h_t$ is Schwartz and we have:

(2.9) \[ \forall s, t > 0 \quad h_t \ast h_s = h_{t+s}, \]

(2.10) \[ \forall x \in G, t, r > 0 \quad h_{r\nu t}(rx) = r^{-\nu}h_t(x), \]

(2.11) \[ \forall x \in G \quad h_t(x) = h_t(x^{-1}), \]

(2.12) \[ \int_G h_t(x)dx = 1. \]

The function $h : G \times \mathbb{R} \to \mathbb{C}$ defined by

$$h(x, t) := \begin{cases} h_t(x) & \text{if } t > 0 \ \text{and} \ x \in G, \\ 0 & \text{if } t \leq 0 \ \text{and} \ x \in G, \end{cases}$$

is smooth on $(G \times \mathbb{R}) \setminus \{(0, 0)\}$ and satisfies $(\mathcal{R} + \partial_t)h = \delta_{0,0}$ where $\delta_{0,0}$ is the delta-distribution at $(0, 0) \in G \times \mathbb{R}$. Having fixed a homogeneous pseudo-norm $| \cdot |$ on $G$, we have for any $N \in \mathbb{N}_0$, $\alpha \in \mathbb{N}_0^n$ and $\ell \in \mathbb{N}_0$:

(2.13) \[ \exists C = C_{\alpha, N, \ell} > 0 \quad \forall t \in (0, 1] \quad \sup_{|x|=1} |\partial_t^\ell X^\alpha h_t(x)| \leq C_{\alpha, N} t^N. \]
Consequently
\[
(2.14) \quad \forall x \in G, \ t > 0 \quad h_t(x) = t^{-\frac{\nu}{2}} h_1(t^{-\frac{1}{2}} x),
\]
and for \( x \in G \setminus \{0\} \) fixed,
\[
(2.15) \quad X^\alpha_x h(x, t) = \begin{cases} 
O(t^{-\frac{Q+1\lfloor\alpha\rfloor}{\nu}}) & \text{as } t \to \infty, \\
O(t^N) & \text{for all } N \in \mathbb{N}_0 \text{ as } t \to 0.
\end{cases}
\]
Inequalities \([2.15]\) are also valid for any \( x \) in a fixed compact subset of \( G \setminus \{0\} \).

Remark 2.10. If the group is stratified and \( R = -L \) where \( L \) is a sub-Laplacian, then \( R \) is of order two and the proof relies on Hunt’s theorem [13], cf. [?, ch1.G]. In this case, the heat kernel is real-valued and moreover non-negative. The heat semigroup is then a semigroup of contraction which preserves positivity.

Theorem 2.9 was proved by Folland and Stein in [4, ch4.B]. In their proof, they also show the following technical property which we will also use later on:

Lemma 2.11. Let \( R \) be a positive Rockland operator of a graded Lie group \( G \sim \mathbb{R}^n \) with homogeneous degree \( \nu \). If \( m \) is a positive integer such that \( m\nu \geq \left\lceil \frac{n}{2} \right\rceil \), then the functions in the domain of \( R^m \) are continuous on \( \Omega \) and for any compact subset \( \Omega \) of \( G \), there exists a constant \( C = C_{\Omega,R,G,m} \) such that
\[
\forall \phi \in \text{Dom}(R^m) \quad \sup_{x \in \Omega} |\phi(y)| \leq C \left( \|\phi\|_{L^2} + \|R^m \phi\|_{L^2} \right).
\]
This is a weak form of Sobolev embeddings. We will later on obtain stronger results of this kind in Theorem 5.2.

We end this section with the following result of Liouville’s type:

Theorem 2.12. If \( R \) is a positive Rockland operator and \( f \in \mathcal{S}'(G) \) a distribution satisfying \( Rf = 0 \) then \( f \) is a polynomial.

Proof. As \( R \) is a positive Rockland operator, \( \mathcal{R} = R' \) is also Rockland and they are both hypoelliptic, see [11]. The conclusion follows by applying the Liouville theorem for homogeneous Lie groups proved by Geller in [7].

\[\square\]

3. Fractional powers of positive Rockland operators

In this section we aim at defining fractional powers of positive Rockland operators. We will carry out the construction on the scale of \( L^p \)-spaces for \( 1 \leq p \leq \infty \), with \( L^\infty(G) \) substituted by the space \( C_0(G) \) of continuous functions vanishing at infinity. Then we discuss the essential properties of such an extension. Eventually we define its complex powers, and the corresponding Riesz and Bessel potentials.
3.1. Positive Rockland operators on $L^p$. Here we define and study the analogue $\mathcal{R}_p$ of the operator $\mathcal{R}$ on $L^p(G)$ or $C_o(G)$. This analogue will be defined as the infinitesimal generator of the heat convolution semigroup. Hence we start by proving the following properties:

**Proposition 3.1.** The operators $f \mapsto f \ast h_t$, $t > 0$, form a strongly continuous semi-group on $L^p(G)$ for any $p \in [1, \infty)$ and on $C_o(G)$ if $p = \infty$. This semi-group is also equibounded:

$$\forall t > 0, \forall f \in L^p(G) \text{ or } C_o(G) \quad \|f \ast h_t\|_p \leq \|h_1\|_1 \|f\|_p.$$  

Furthermore for any $p \in [1, \infty]$ (finite or infinite) and any $f \in \mathcal{D}(G)$,  

$$\lim_{t \to 0} \left\| \frac{1}{t} (f \ast h_t - f) - \mathcal{R}f \right\|_p = 0.$$  

**Proof of Proposition 3.1.** If $f \in \mathcal{D}(G)$, then $f \in \text{Dom}(\mathcal{R}) \subset \text{Dom}(\mathcal{R}_2)$ and for any $s, t > 0$, by functional calculus,

$$f \ast h_{t+s} = e^{-(t+s)\mathcal{R}_2} f = e^{-t\mathcal{R}_2} e^{-s\mathcal{R}_2} f = (f \ast h_s) \ast h_t$$

and, by the Young convolution inequalities for $p \in [1, \infty]$ (see (2.2)),

$$\|f \ast h_t\|_p \leq \|h_t\|_1 \|f\|_p$$

with $\|h_t\|_1 = \|h_1\|_1 < \infty$ by Theorem 2.9. By density of $\mathcal{D}(G)$ in $L^p(G)$ for $p \in [1, \infty)$ and $C_o(G)$ for $p = \infty$, this implies that the operators $f \mapsto f \ast h_t$, $t > 0$, form a strongly continuous equibounded semi-group on $L^p(G)$ for any $p \in [1, \infty)$ and on $C_o(G)$.

Let us prove the convergence in (3.1) for $p = \infty$. Let $f \in \mathcal{D}(G)$. By Lemma 2.11, for any compact subset $\Omega \subset G$,

$$\sup_{\Omega} \left| \frac{1}{t} (f \ast h_t - f) - \mathcal{R}f \right| \leq C \left( \left\| \frac{1}{t} (f \ast h_t - f) - \mathcal{R}f \right\|_2 + \left\| \frac{1}{t} \mathcal{R}^m (f \ast h_t - f) - \mathcal{R}^{m+1} f \right\|_2 \right),$$

where $m$ is an integer such that $mv \geq \left\lceil \frac{n}{2} \right\rceil$. Since $\mathcal{D}(G) \subset \text{Dom}(\mathcal{R})$ and $e^{-t\mathcal{R}_2} f = f \ast h_t$, we have for any integer $m' \in \mathbb{N}_0$:

$$\frac{1}{t} \mathcal{R}^{m'} (f \ast h_t - f) - \mathcal{R}^{m'+1} f = \frac{1}{t} \mathcal{R}_2^{m'} (e^{-t\mathcal{R}_2} f - f) - \mathcal{R}_2^{m'+1} f$$

$$= \frac{1}{t} (e^{-t\mathcal{R}_2} \mathcal{R}_2^{m'} f - \mathcal{R}_2^{m'} f) - \mathcal{R}_2^{m'+1} f = \frac{1}{t} ((\mathcal{R}_2^{m'} f) \ast h_t - \mathcal{R}_2^{m'} f) - \mathcal{R}_2^{m'+1} f.$$  

This last expression converges to zero in $L^2(G)$ as $t \to 0$. Therefore

$$\sup_{\Omega} \left| \frac{1}{t} (f \ast h_t - f) - \mathcal{R}f \right| \to_{t \to 0} 0.$$

We fix a homogeneous pseudo-norm $|\cdot|$ on $G$, for example the one in Part (3) of Proposition 2.1. We denote by $\bar{B}_R := \{x \in G, \ |x| \leq R\}$ the closed ball about 0 of radius $R$. We now fix
R \geq 1$ such that $B_R$ contains the support of $f$. Let $C_0 = C_b$ be the constant in the reverse triangle inequality, see (2.3), for $b = \frac{1}{2}$. We choose $\Omega = \overline{B_{2C_0 R}}$ the closed ball about $0$ and with radius $2C_0 R$. If $x \not\in \Omega$, then since $f$ is supported in $B_R \subset \Omega$, 

$$
\left( \frac{1}{t} (f * h_t - f) - \mathcal{R} f \right)(x) = \frac{1}{t} f * h_t(x) = \frac{1}{t} \int_{|y| \leq R} f(y) h_t(y^{-1} x) dy,
$$

hence 

$$
\left| \frac{1}{t} f * h_t(x) \right| \leq \frac{\|f\|_{L^\infty}}{t} \int_{|y| \leq R} |h_t(y^{-1} x)| dy = \frac{\|f\|_{L^\infty}}{t} \int_{|xt^{-1} z^{-1}| \leq R} |h_1(z)| dz,
$$

as $h_t$ satisfies (2.14). The reverse triangle inequality, see (2.3), implies $\{ |xt^{-1} z^{-1}| \leq R \} \subset \{|z| > t^{-\frac{1}{2}} R/2 \}$. Since $h_1$ is Schwartz, we must have 

$$
\exists C \quad |h_1(z)| \leq C |z|^{-\alpha},
$$

for $\alpha = -Q - 2\nu$ for instance. This together with the polar change of variable (see Proposition 2.2) yield 

$$
\int_{|z| > t^{-\frac{1}{2}} R/2} |h_1(z)| dz \leq C \int_{r = t^{-\frac{1}{2}} R/2}^\infty r^{-\alpha - Q - 1} dr = C' t^2.
$$

Consequently taking the supremum in the complementary on $\Omega$ 

$$
\sup_{\Omega^c} \left| \frac{1}{t} (f * h_t - f) - \mathcal{R} f \right| \leq C' t \longrightarrow_{t \to 0} 0.
$$

This shows the convergence in (3.1) for $p = \infty$.

We now proceed in a similar way to prove the convergence in (3.1) for $p$ finite. As above we fix $f \in \mathcal{D}(G)$ supported in $B_R$. We decompose 

$$
\| \frac{1}{t} (f * h_t - f) - \mathcal{R} f \|_p \leq \| \frac{1}{t} (f * h_t - f) - \mathcal{R} f \|_{L^p(B_{2C_0 R})} + \| \frac{1}{t} (f * h_t - f) - \mathcal{R} f \|_{L^p(B_{2C_0 R})}.
$$

For the first term, 

$$
\| \frac{1}{t} (f * h_t - f) - \mathcal{R} f \|_{L^p(B_{2C_0 R})} \leq |\overline{B}_{2C_0 R}|^{\frac{1}{p}} \| \frac{1}{t} (f * h_t - f) - \mathcal{R} f \|_{\infty} \longrightarrow_{t \to 0} 0,
$$

as we have already proved the convergence in (3.1) for $p = \infty$. For the second term, we obtain for the reasons explained in the case $p = \infty$: 

$$
\| \frac{1}{t} (f * h_t - f) - \mathcal{R} f \|_{L^p(B_{2C_0 R})} = \frac{1}{t} \| f * h_t \|_{L^p(B_{2C_0 R})} 
\leq C_{0,2} \frac{\|f\|_{L^\infty}}{t} \left( \int_{|x| > 2C_0 R} \int_{|y| < R} \left| h_1(x) \right| dz \right)^{\frac{1}{p}} \leq C_{0,2} \frac{\|f\|_{L^\infty}}{t} \left( C' t^p \right)^{\frac{1}{p}},
$$

choosing this time $\alpha = -Q - \nu \nu$. This yields the convergence in (3.1) for $p$ finite. \qed
Definition 3.2. Let $\mathcal{R}$ be a positive Rockland operator on $G$.

For $p \in [1, \infty)$, we denote by $\mathcal{R}_p$ the operator such that $-\mathcal{R}_p$ is the infinitesimal generator of the semi-group of operators $f \mapsto f * h_t$, $t > 0$, on the Banach space $L^p(G)$.

We also denote by $\mathcal{R}_\infty$ the operator such that $-\mathcal{R}_\infty$ is the infinitesimal generator of the semi-group of operators $f \mapsto f * h_t$, $t > 0$, on the Banach space $C_o(G)$.

For the moment it seems that $\mathcal{R}_2$ denotes the self-adjoint extension of $\mathcal{R}$ on $L^2(G)$ and minus the generator of $f \mapsto f * h_t$, $t > 0$, on $L^2(G)$. In the sequel, in fact in Theorem 3.3 below, we show that the two operators coincide and there is no conflict of notation.

**Theorem 3.3.** Let $\mathcal{R}$ be a positive Rockland operator on $G$ and $p \in [1, \infty) \cup \{\infty_o\}$.

(i) The operator $\mathcal{R}_p$ is closed. The domain of $\mathcal{R}_p$ contains $\mathcal{D}(G)$, and for $f \in \mathcal{D}(G)$ we have $\mathcal{R}_p f = \mathcal{R} f$.

(ii) The operator $\mathcal{R}_p$ is positive and Rockland. Moreover $-\mathcal{R}_p$ is the infinitesimal generator of the strongly continuous semi-group $\{f \mapsto f * h_t\}_{t>0}$ on $L^p(G)$ for $p \in [1, \infty)$ and on $C_o(G)$ for $p = \infty_o$.

(iii) If $p \in (1, \infty)$ then the dual of $\mathcal{R}_p$ is $\mathcal{R}_p'$. The dual of $\mathcal{R}_\infty$ restricted to $L^1(G)$ is $\mathcal{R}_1$. The dual of $\mathcal{R}_1$ restricted to $C_o(G) \subset L^\infty(G)$ is $\mathcal{R}_\infty$.

(iv) If $p \in [1, \infty)$, the operator $\mathcal{R}_p$ is the maximal restriction of $\mathcal{R}$ to $L^p(G)$, that is, the domain of $\mathcal{R}_p$ consists of all the functions $f \in L^p(G)$ such that the distributional derivative $\mathcal{R} f$ is in $L^p(G)$ and $\mathcal{R}_p f = \mathcal{R} f$.

The operator $\mathcal{R}_\infty$ is the maximal restriction of $\mathcal{R}$ to $C_o(G)$, that is, the domain of $\mathcal{R}_\infty$ consists of all the function $f \in C_o(G)$ such that the distributional derivative $\mathcal{R} f$ is in $C_o(G)$ and $\mathcal{R}_p f = \mathcal{R} f$.

(v) If $p \in [1, \infty)$, the operator $\mathcal{R}_p$ is the smallest closed extension of $\mathcal{R}|_{\mathcal{D}(G)}$ on $L^p(G)$. For $p = 2$, $\mathcal{R}_2$ is the self-adjoint extension of $\mathcal{R}$ on $L^2(G)$.

**Proof.** Part (i) is a consequence of Proposition 3.1. Intertwining with the complex conjugate, this implies that $\{f \mapsto f * h_t\}_{t>0}$ is also a strongly continuous semi-group on $L^p(G)$ whose infinitesimal operator coincides with $-\bar{\mathcal{R}} = -\mathcal{R}'$ on $\mathcal{D}(G)$. This shows Part (ii).

For Part (iii), we observe that using (2.1) and (2.11), we have

$$\langle f_1, f_2 \rangle = \langle f_1 \ast h_t, f_2 \rangle = \langle f_1, f_2 \ast \bar{h}_t \rangle.$$  

Thus we have for any $f, g \in \mathcal{D}(G)$ and $p \in [1, \infty) \cup \{\infty_o\}$

$$\langle \frac{1}{t} (e^{-t\mathcal{R}_p} f - f), g \rangle = \frac{1}{t} \langle f \ast h_t - f, g \rangle = \frac{1}{t} \langle f, g \ast \bar{h}_t - g \rangle = \frac{1}{t} \langle f, e^{-t\mathcal{R}_p} g - g \rangle.$$  

Here the brackets refer to the duality in the sense of distribution. Taking the limit as $t \to 0$ of the first and last expressions proves Part (iii).

We now prove Part (iv) for any $p \in [1, \infty) \cup \{\infty_o\}$. Let $f \in \text{Dom}(\mathcal{R}_p)$ and $\phi \in \mathcal{D}(G)$. Since $\mathcal{R}$ is formally self-adjoint, we know that $\mathcal{R}^t = \bar{\mathcal{R}}$, and by Part (i), we have $\mathcal{R}_q \phi = \mathcal{R} \phi$.
for any $q \in [1, \infty) \cup \{\infty_{o}\}$. Thus by Part (iii) we have
\[ \langle R_p f, \phi \rangle = \langle f, R_p \phi \rangle = \langle f, R^t \phi \rangle = \langle R f, \phi \rangle, \]
and $R_p f = R f$ in the sense of distributions. Thus
\[ \text{Dom}(R_p) \subset \{ f \in L^p(G) : Rf \in L^p(G) \}. \]

We now prove the reverse inclusion. Let $f \in L^p(G)$ such that $Rf \in L^p(G)$. Let also $\phi \in D(G)$. The following computations are justified by the properties of $R$ and $h_t$ (see Theorem [2.9], Fubini’s Theorem, and (3.2):
\[
\langle f * h_t - f, \phi \rangle = \langle f, \phi * \bar{h}_t - \phi \rangle = \langle f, \int_0^t \partial_s (\phi * \bar{h}_s) ds \rangle = \langle f, \int_0^t -R(\phi * \bar{h}_s) ds \rangle
\]
\[= -\langle f, R \int_0^t (\phi * \bar{h}_s) ds \rangle = -\langle Rf, \int_0^t \phi * \bar{h}_s ds \rangle = -\int_0^t \langle Rf, \phi * \bar{h}_s \rangle ds
\]
\[= -\int_0^t \langle (Rf) * h_s, \phi \rangle ds = -\int_0^t \langle (Rf) * h_s ds, \phi \rangle. \]
Therefore,
\[\frac{1}{t} (f * h_t - f) = \frac{1}{t} \int_0^t (Rf) * h_s ds. \]
This converges towards $-Rf$ in $L^p(G)$ as $t \to 0$ by the general properties of averages of strongly continuous semigroups on a Banach space. This shows $f \in \text{Dom}(R_p)$ and concludes the proof of (iv).

Part (v) follows from (iv). This also shows that the self-adjoint extension of $R$ coincides with $R_2$ as defined in Definition [3.2] and concludes the proof of Theorem [3.3].

Theorem [3.3] has the following consequences which will enable us to define the fractional powers of $R_p$.

**Corollary 3.4.** We keep the same setting and notation as in Theorem [3.3].

(i) The operator $R_p$ is injective on $L^p(G)$ for $p \in [1, \infty)$ and $R_{\infty_{o}}$ is injective on $C_o(G)$, namely,

\[ \text{for } p \in [1, \infty) \cup \{\infty_{o}\} : \forall f \in \text{Dom}(R_p) \quad R_p f = 0 \implies f = 0. \]

(ii) If $p \in (1, \infty)$ then the operator $R_p$ has dense range in $L^p(G)$. The operator $R_{\infty_{o}}$ has dense range in $C_o(G)$. The closure of the range of $R_1$ is the closed subspace \{ $\phi \in L^1(G) : \int_G \phi = 0$ \} of $L^1(G)$.

(iii) For $p \in [1, \infty) \cup \{\infty_{o}\}$, and any $\mu > 0$, the operator $\mu I + R_p$ is invertible on $L^p(G)$, $p \in [1, \infty)$, and on $C_o(G)$ for $p = \infty_{o}$, and the operator norm of $(\mu I + R_p)^{-1}$ is

\[ \| (\mu I + R_p)^{-1} \|_{\mathcal{L}(L^p(G))} \leq \| h_1 \| \mu^{-1} \quad \text{or} \quad \| (\mu I + R_{\infty_{o}})^{-1} \|_{\mathcal{L}(C_o(G))} \leq \| h_1 \| \mu^{-1}. \]

(3.3)
Proof. Let \( f \in \text{Dom}(\mathcal{R}_p) \) be such that \( \mathcal{R}_p f = 0 \) for \( p \in [1, \infty) \cup \{\infty_o\} \). By Theorem 3.3 (iv), \( f \in \mathcal{S}'(G) \) and \( \mathcal{R} f = 0 \). Consequently by Liouville’s theorem, see Theorem 2.12, \( f \) is a polynomial. Since \( f \) is also in \( L^p(G) \) for \( p \in [1, \infty) \) or in \( C_o(G) \) for \( p = \infty_o \), \( f \) must be identically zero. This proves (i).

For (ii), let \( \Psi \) be a bounded linear functional on \( L^p(G) \) if \( p \in [1, \infty) \) or on \( C_o(G) \) if \( p = \infty_o \) such that \( \Psi \) vanishes identically on \( \text{Range}(\mathcal{R}_p) \). Then \( \Psi \) can be realised as the integration against a function \( f \in L^p(G) \) if \( p \in [1, \infty) \) or a measure also denoted by \( f \in M(G) \) if \( p = \infty_o \). Using the distributional notation, we have

\[
\Psi(\phi) = \langle f, \phi \rangle \quad \forall \phi \in L^p(G) \quad \text{or} \quad \forall \phi \in C_o(G).
\]

Then for any \( \phi \in \mathcal{D}(G) \), we know that \( \phi \in \text{Dom}(\mathcal{R}_p) \) and \( \mathcal{R}_p \phi = \mathcal{R} \phi \) by Theorem 3.3 (i) thus

\[
0 = \Psi(\mathcal{R}_p(\phi)) = \langle f, \mathcal{R}(\phi) \rangle = \langle \mathcal{R} f, \phi \rangle,
\]

since \( \mathcal{R}^t = \mathcal{R} \). Hence \( \mathcal{R} f = 0 \). By Liouville’s theorem, see Theorem 2.12, this time applied to the positive Rockland operator \( \mathcal{R} \), we see that \( f \) is a polynomial. This implies that \( f \equiv 0 \), since \( f \) is also a function in \( L^p(G) \) in the case \( p \in (1, \infty) \), whereas for \( p = \infty_o \), \( f \) is in \( M(G) \) thus an integrable polynomial on \( G \). For \( p = 1 \), \( f \) being a measurable bounded function and a polynomial, \( f \) must be constant, i.e. \( f \equiv c \) for some \( c \in \mathbb{C} \). This shows that if \( p \in (1, \infty) \cup \{\infty_o\} \) then \( \Psi = 0 \) and \( \text{Range}(\mathcal{R}_p) \) is dense in \( L^p(G) \) or \( C_o(G) \), whereas if \( p = 1 \) then \( \Psi : L^1(G) \ni \phi \mapsto c \int_G \phi \). This shows (ii) for \( p \in (1, \infty) \cup \{\infty_o\} \).

Let us study more precisely the case \( p = 1 \). It is easy to see that

\[
\int_G X\phi(x)dx = -\int_G \phi(x)(X1)(x)dx = 0
\]

holds for any \( \phi \in L^1(G) \) such that \( X\phi \in L^1(G) \). Consequently, for any \( \phi \in \text{Dom}(\mathcal{R}_1) \), we know that \( \phi \) and \( \mathcal{R} \phi \) are in \( L^1(G) \) thus \( \int_G \mathcal{R}_1 \phi = 0 \). So the range of \( \mathcal{R}_1 \) is included in

\[
S := \{ \phi \in L^1(G) : \int_G \phi = 0 \} \supset \text{Range}(\mathcal{R}_1).
\]

Moreover, if \( \Psi_1 \) a bounded linear functional on \( S \) such that \( \Psi_1 \) is identically 0 on \( \text{Range}(\mathcal{R}_1) \), by the Hahn-Banach Theorem, it can be extended into a bounded linear function \( \Psi \) on \( L^1(G) \). As \( \Psi \) vanishes identically on \( \text{Range}(\mathcal{R}_1) \subset S \), we have already proven that \( \Psi \) must be of the form \( \Psi : L^1(G) \ni \phi \mapsto c \int_G \phi \) for some constant \( c \in \mathbb{C} \) and its restriction to \( S \) is \( \Psi_1 \equiv 0 \). This concludes the proof of Part (ii).

Let us prove Part (iii). Integrating the formula

\[
(\mu + \lambda)^{-1} = \int_0^\infty e^{-t(\mu+\lambda)}dt
\]
against the spectral measure $dE(\lambda)$ of $\mathcal{R}_2$, we have formally

\begin{equation}
(\mu I + \mathcal{R}_2)^{-1} = \int_0^\infty e^{-t(\mu I + \mathcal{R}_2)} dt,
\end{equation}

and the convolution kernel of the operator on the right-hand side is (still formally) given by

$$\kappa_\mu(x) := \int_0^\infty e^{-t\mu} h_t(x) dt.$$ 

From the properties of the heat kernel $h_t$ (see Theorem 2.9), we see that $\kappa_\mu$ is continuous on $G$ and that

$$\|\kappa_\mu\|_1 \leq \int_0^\infty e^{-t\mu} \|h_t\|_1 dt = \|h_1\| \int_0^\infty e^{-t\mu} dt = \frac{\|h_1\|}{\mu} < \infty.$$ 

Therefore $\kappa_\mu \in L^1(G)$ and the operator $\int_0^\infty e^{-t(\mu I + \mathcal{R}_2)} dt$ is bounded on $L^2(G)$. Furthermore Formula (3.4) holds (it suffices to consider integration over $[0,N]$ with $N \to \infty$).

For any $\phi \in \mathcal{D}(G)$ and $p \in [1,\infty) \cup \{\infty\}$, Theorem 3.3 (iv) implies

$$(\mu I + \mathcal{R}_p)\phi = (\mu I + \mathcal{R})\phi = (\mu I + \mathcal{R}_2)\phi \in \mathcal{D}(G),$$

thus

$$\kappa_\mu * ((\mu I + \mathcal{R}_p)\phi) = \kappa_\mu * ((\mu I + \mathcal{R}_2)\phi) = \phi.$$ 

Hence the inverse of the operator $\mu I + \mathcal{R}_p$ coincide with the convolution operator $\phi \mapsto \phi * \kappa_\mu$ which is bounded on $L^p(G)$ if $p \in [1,\infty)$ and on $C_o(G)$ if $p = \infty$. Furthermore the operator norm of the latter is $\leq \|\kappa_\mu\|_1 \leq \|h_1\|\mu^{-1}$.  

### 3.2. Fractional powers of operators $\mathcal{R}_p$. In this section we study the fractional powers of the operators $\mathcal{R}_p$ and $I + \mathcal{R}_p$.

**Theorem 3.5.** Let $\mathcal{R}$ be a positive Rockland operator on a graded group $G$. We consider the operators $\mathcal{R}_p$ defined in Definition 3.2. Let $p \in [1,\infty) \cup \{\infty\}$.

1. Let $\mathcal{A}_p$ denote either $\mathcal{R}_p$ or $I + \mathcal{R}_p$.
   - For every $a \in \mathbb{C}$, the operator $\mathcal{A}_p^a$ is closed and injective with $(\mathcal{A}_p^a)^{-1} = \mathcal{A}_p^{-a}$. We have $\mathcal{A}_p^0 = I$, and for any $n \in \mathbb{N}$, $\mathcal{A}_p^n$ coincides with the usual powers of differential operators on $\mathcal{D}(G)$. Furthermore, the operator $\mathcal{A}_p^a$ is invariant under left translations.
   - For any $a,b \in \mathbb{C}$, in the sense of operator graph, we have $\mathcal{A}_p^a \mathcal{A}_p^b \subset \mathcal{A}_p^{a+b}$. If $p \neq 1$ then the closure of $\mathcal{A}_p^a \mathcal{A}_p^b$ is $\mathcal{A}_p^{a+b}$.
   - Let $a_o \in \mathbb{C}_+$. If $\phi \in \text{Range}(\mathcal{A}_p^{a_o})$ then $\phi \in \text{Dom}(\mathcal{A}_p^a)$ for all $a \in \mathbb{C}$ with $-\text{Re} \ a_o < \text{Re} \ a < 0$ and the function $a \mapsto \mathcal{A}_p^a \phi$ is holomorphic in $\{a \in \mathbb{C} : -\text{Re} \ a_o < \text{Re} \ a < 0\}$. 

and \( Bx \) and for any \( \tau \)
- If \( \phi \in \operatorname{Dom}(A^a) \) then \( \phi \in \operatorname{Dom}(A^a) \) for all \( a \in \mathbb{C} \) with \( 0 < \Re a < \Re a_0 \) and the function \( a \mapsto A^a \phi \) is holomorphic in \( \{ a \in \mathbb{C} : 0 < \Re a < \Re a_0 \} \).
- If \( p \in (1, \infty) \) then the dual of \( A'_p \) is \( A_p' \). The dual of \( A'_\infty \) restricted to \( L^1(G) \) is \( A_1 \). The dual of \( A_1 \) restricted to \( C_0(G) \subset L^\infty(G) \) is \( A_{\infty_0} \).
- If \( a, b \in \mathbb{C}_+ \) with \( \Re b > \Re a \), then 
  \[
  \exists C = C_{a,b} > 0 \quad \forall \phi \in \operatorname{Dom}(A^b) \quad \| A^a_\phi \| \leq C \| \phi \| e^{-\Re \epsilon a} \| A^b_\phi \| e^{\Re \epsilon b}.
  \]

(2) For each \( a \in \mathbb{C}_+ \), the operators \( (I + R_p)^a \) and \( R_p^a \) are unbounded and their domains satisfy \( \operatorname{Dom}[(I + R_p)^a] = \operatorname{Dom}(R_p^a) = \operatorname{Dom}[(R_p + \epsilon I)^a] \) for all \( \epsilon > 0 \), and all these domains contain \( S(G) \).

(3) If \( 0 < \Re a < 1 \) and \( \phi \in \operatorname{Range}(R_p) \) then 
  \[
  R_p^{-a} \phi = \frac{1}{\Gamma(a)} \int_0^\infty t^{a-1} e^{-t} R_p t \phi dt,
  \]
  in the sense that \( \lim_{N \to \infty} \int_0^N \) converges in the norm of \( L^p(G) \) or \( C_0(G) \).

(4) If \( a \in \mathbb{C}_+ \), then the operator \( (1 + R_p)^{-a} \) is bounded and for any \( \phi \in \mathcal{X} \) with \( \mathcal{X} = L^p(G) \) or \( C_0(G) \), we have 
  \[
  (I + R_p)^{-a} \phi = \frac{1}{\Gamma(a)} \int_0^\infty t^{a-1} e^{-t} (1 + R_p) t \phi dt,
  \]
  in the sense of absolute convergence: \( \int_0^\infty t^{a-1} \| e^{-t} (1 + R_p) t \phi \| \mathcal{X} dt < \infty \).

(5) For any \( \tau \in \mathbb{R} \) and \( p \in (1, \infty) \), the operator \( R_p^{i\tau} \) is bounded on \( L^p(G) \). Moreover 
  \[
  \exists C, \theta > 0 \quad \forall \tau \in \mathbb{R} \quad \| R_p^{i\tau} \|_{L^p(G)} \leq Ce^{\theta |\tau|}.
  \]
  and for any \( a \in \mathbb{C} \),
  \[
  \operatorname{Dom}(R_p^a) = \operatorname{Dom}(R_p^{\Re a}).
  \]

(6) For any \( \tau \in \mathbb{R} \) and \( p \in (1, \infty) \), the operator \( (I + R_p)^{i\tau} \) is bounded on \( L^p(G) \). Moreover 
  \[
  \exists C, \theta > 0 \quad \forall \tau \in \mathbb{R} \quad \| (I + R_p)^{i\tau} \|_{L^p(G)} \leq Ce^{\theta |\tau|}.
  \]
  and for any \( a \in \mathbb{C} \),
  \[
  \operatorname{Dom}((I + R_p)^a) = \operatorname{Dom}((I + R_p)^{\Re a}).
  \]

(7) For any \( a, b \in \mathbb{C} \), the two (possibly unbounded) operators \( R_p^a \) and \( (I + R_p)^b \) commute.

(8) For any \( a \in \mathbb{C} \), the operator \( R_p^a \) is homogeneous of degree \( va \).

Here we say that two (possibly unbounded) operators \( A \) and \( B \) commute when 
  \[
  x \in \operatorname{Dom}(AB) \cap \operatorname{Dom}(BA) \implies ABx = BAx.
  \]
Let us recall that the domain of the product \( AB \) of two (possibly unbounded) operators \( A \) and \( B \) on the same Banach space \( \mathcal{X} \) is formed by the elements \( x \in \mathcal{X} \) such that \( x \in \operatorname{Dom}(B) \) and \( Bx \in \operatorname{Dom}(A) \).
In Theorem 3.5 Part (3), $\Gamma$ denotes the usual Gamma function.

**Proof.** By Theorem 3.3 (i), the operator $R_p$ is closed and densely defined. By Corollary 3.4, it is injective and Komatsu-non-negative in the sense that $(-\infty, 0)$ is included in its resolvant set and it satisfies Property (3.3). Necessarily $I + R_p$ also satisfies these properties. Furthermore $-(I + R_p)$ generates an exponentially stable semigroup:

$$\|e^{-t(I+R_p)}\|_{L^p(G)} \leq e^{-t}\|e^{-tR_p}\|_{L^p(G)} \leq e^{-t}\|h_1\|_1,$$

and similarly for $C_0(G)$.

Most of the statements then follow from the general properties of fractional powers. References for these results are in [14] as follows: for Part (1) Corollaries 5.2.4, 5.1.12, and 5.1.13, together with and Section 7.1, for Parts (3) and (4) Lemma 6.1.5, for Part (5) Section 7.1 and Corollary 7.1.2. For Part (2), the property that the domains coincide comes from [14, Theorem 5.1.7]. That they contain $S(G)$ and that the operators are unbounded is true for integer powers, hence true using Part (1).

This concludes the proof of Theorem 3.5, except for Parts (5) and (6). For the moment, let us admit that all the operators $R^{i\tau}_p$, $\tau \in \mathbb{R}$, are bounded. Then for any $a \in \mathbb{C}$, $R^{a+i\tau}_p$ is the closure of $R^i_p R^a_p$ by Part (1), so $\text{Dom}(R^{a+i\tau}_p) \supset \text{Dom}(R^a_p)$. Applying this to $a \in \mathbb{R}$ and $a - i\tau$, this shows $\text{Dom}(R^{a}_p) = \text{Dom}(R^{Re a'}_p)$ for any $a' \in \mathbb{C}$. By Part (2), we must also have $\text{Dom}(I + R_p)^{a'} = \text{Dom}(I + R_p)^{Re a'}$ for any $a' \in \mathbb{C}$. Now by Part (1), for any $\tau \in \mathbb{R}$, we have in the sense of operators

$$(I + R_p)^{i\tau} \supset (I + R_p)(I + R_p)^{1-i\tau} \quad \text{and} \quad I \supset (I + R_p)^{1-i\tau}(I + R_p)^{-1+i\tau},$$

hence

$$\text{Range}(I + R_p)^{-1+i\tau} \subset \text{Dom}(I + R_p)^{1-i\tau} = \text{Dom}(I + R_p),$$

so

$$\text{Dom}(I + R_p)^{i\tau} \supset \text{Dom}(I + R_p)^{-1+i\tau}.$$ 

This last domain is the whole space $L^p$ since $(I + R_p)^{-1+i\tau}$ is bounded by Part (4). Then the closed graph theorem implies that $(I + R_p)^{i\tau}$ is bounded. The bounds for the operator norms of $R^{i\tau}_p$ and $(I + R_p)^{i\tau}$ comes from [14, Proposition 8.1.1].

Hence the proof of Theorem 3.5 will be complete once we have proved that each operator $R^{i\tau}_p$, $\tau \in \mathbb{R}$, is bounded. This will require a couple of technical lemmata.

**Lemma 3.6.** Let $R$ be a positive Rockland operator on $G$, with heat kernels $h_t$. For each $a \in \mathbb{C}$ with $|\text{Re} a| < 1$ and $x \neq 0$, the integral

$$\frac{1}{\Gamma\left(\frac{a}{p} + 1\right)} \int_0^\infty t^{\frac{a}{p}} R h_t(x) dt$$

is absolutely convergent for every $x \neq 0$. This defines kernel of type $a$.  

---

1 ref?
Lemma 3.7. We keep the setting and notation of Theorem 3.3. For any $R_m \equiv 0$ must be identically zero. This shows that $\Psi$ by Liouville’s Theorem to 

Proof of Lemma 3.7. Moreover choosing e.g. $b_2 = 2b_1$ and $b_1 = \ell^{-1}$ for every $\ell \in \mathbb{N}$, we have $|m_{\kappa_a}| \leq C_{r,b} \ell^{-Q+1}$, hence $m_{\kappa_a} = 0$. Hence by Definition 2.3 and Proposition 2.5 $\kappa_a$ is a kernel of type $a$.

We will also need the following technical result:

Lemma 3.7. We keep the setting and notation of Theorem 3.3. For any $N \in \mathbb{N}$, the space $R_N(S(G)) = R_p^N(S(G))$ is contained in $\text{Dom}(R^N_p) \cap \text{Range}(R^N_p)$ and in $S(G)$. The space $R_p^N(S(G))$ is dense in $L^p(G)$ if $p \in (1, \infty)$, and $R_{\infty,o}^N(S(G))$ is dense in $C_o(G)$.

Proof of Lemma 3.7. By Theorem 3.3 Part (iv),

$S(G) \subset \text{Dom}(R^N_p)$ and $R_p^N(S(G)) = R^N(S(G)) \subset S(G)$.

It remains to prove the properties of density. For this we proceed as in the proof of Corollary 3.4. Let $\Psi$ be a bounded linear functional on $L^p(G)$ if $p \in (1, \infty)$ or on $C_o(G)$ if $p = \infty_o$ such that $\Psi$ vanishes identically on $R^N_p(S(G))$. Realising $\Psi$ as the integration against a function $f \in L^p(G)$ if $p \in (1, \infty)$ or $f \in M(G)$ if $p = \infty_o$, we have $R^N f = 0$. Applying Liouville’s Theorem to $R^{N_1}$ (see Theorem 2.12), this shows that $f$ is a polynomial hence it must be identically zero. This shows that $\Psi \equiv 0$ and $R_p^N(S(G))$ is dense in $L^p(G)$. 

We can now prove Part (5) of Theorem 3.5.

Proof of Part (5) of Theorem 3.5. We keep the notation of Lemma 3.6 and its proof. The function $\kappa_a$ defined via (3.5) is smooth away from the origin, $(a-Q)$-homogeneous, and with mean average 0 if $a \in i\mathbb{R}$. We assume $\text{Re} a \in [0, Q)$. By Theorem 2.4 and Proposition 2.5 the operator $f \mapsto f * \kappa_a$ is bounded from $L^q(G)$ to $L^p(G)$ where $\frac{1}{q} - \frac{1}{p} = \frac{\text{Re} a}{Q}$, $p, q \in (1, \infty)$. 

By Lemma \[3.7\] we can apply the analyticity results of Theorem \[3.5\] for \( \phi \in \mathcal{R}_p(\mathcal{S}(G)) \), \( a \mapsto \mathcal{R}_p^{-\frac{a}{p}} \phi \) is holomorphic on the strip \( \{ a \in \mathbb{C} : |\text{Re}\, \frac{a}{p}| < 1 \} \). Furthermore, by Theorem \[3.5\] (3), if \( 0 < \text{Re}\, \frac{a}{p} < 1 \), we have, with convergence in \( L^p(G) \),

\[
\mathcal{R}_p^{-\frac{a}{p}} \phi = \lim_{R \to \infty} \frac{1}{\Gamma(\frac{a}{p})} \int_0^R t^{\frac{a}{p}-1} \phi * h_t dt.
\]

Integrating by parts, we get

\[
\int_0^R t^{\frac{a}{p}-1} \phi * h_t dt = \left[ \frac{t^{\frac{a}{p}}}{\frac{a}{p}} \phi * h_t \right]_0^R - \int_0^R \frac{t^{\frac{a}{p}}}{\frac{a}{p}} \partial_t (\phi * h_t) dt.
\]

Now the first term (the bracket) at \( t = 0 \) gives 0 since \( \text{Re} \, \frac{a}{p} > 0 \) and so that the first term at \( R \) gives 0 as \( R \to \infty \), for \( \text{Re} \, a < Q(1 - \frac{1}{p}) \). For the first term at \( t = R \), by the property of homogeneity of \( h_t \) (see (2.14)), we have

\[
\| \phi * h_t \|_p \leq t^{-\frac{Q}{p}} \| h_1 \circ D_{t^{-\frac{1}{p}}} \|_p \| \phi \|_1 = t^{-\frac{Q}{p}} t^{\frac{Q}{p}} \| h_1 \|_p \| \phi \|_1,
\]

so that the first term at \( R \) gives 0 as \( R \to \infty \), for \( \text{Re} \, a < Q(1 - \frac{1}{p}) \). For the second term in the right-hand side of (3.6), as \( \partial_t (\phi * h_t) = \phi * \partial h_t = \phi * \mathcal{R} h_t \), we have

\[
\frac{1}{\Gamma(\frac{a}{p})} \int_0^R \frac{t^{\frac{a}{p}}}{\frac{a}{p}} \partial_t (\phi * h_t) dt = \frac{1}{\Gamma(1 + \frac{a}{p})} \phi * \int_0^R t^{\frac{a}{p}} \mathcal{R} h_t dt.
\]

By Lemma \[3.6\] if \( \text{Re} \, a < Q \), this converges to \( \phi * \kappa_a \) in \( L^p(G) \) as \( R \to \infty \) since by the first part of this proof, we have

\[
\| \phi * \kappa_a \|_{L^p(G)} \leq C \| \phi \|_{L^q(G)}.
\]

We have obtained that for each \( \phi \in \mathcal{R}_p(\mathcal{S}(G)) \), \( a \mapsto \mathcal{R}_p^{-\frac{a}{p}} \phi \) is holomorphic on the strip \( \{ |\text{Re}\, \frac{a}{p}| < 1 \} \) and coincides with \( a \mapsto \phi * \kappa_a \) on \( \{ 0 < \text{Re} \, a < Q(1 - \frac{1}{p}) \} \). It is easy to check that \( a \mapsto \phi * \kappa_a \) is holomorphic on the strip \( \{ 0 < \text{Re} \, a < Q \} \) and continuous on \( \{ 0 \leq \text{Re} \, a < Q \} \). This implies that, for \( \text{Re} \, a = 0 \), the closed operator \( \mathcal{R}_p^{-\frac{a}{p}} \) and the bounded operator \( \phi \mapsto \phi * \kappa_a \) coincide on the dense subspace \( \mathcal{R}_p(\mathcal{S}(G)) \), the latter convolution operator being bounded on \( L^p(G) \) by Theorem \[2.4\] and Proposition \[2.5\] Thus for \( \text{Re} \, a = 0 \) the operator \( \mathcal{R}_p^{-\frac{a}{p}} \) is bounded and is the convolution operator with kernel \( \kappa_a \). This concludes the proof of Part \[5\] of Theorem \[3.5\] and of the whole theorem.

**Remark 3.8.** The bound for \( \| \mathcal{R}_p^{i\tau} \|_{\mathcal{L}(L^p)} \) given in Theorem \[3.5\] (5) may be improved by tracking down the various constants in the proof above and in the proof of Theorem \[2.4\]. In the case of a sub-Laplacian, that is, \( G \) stratified and \( \mathcal{R} = -\mathcal{L} \), using another argument, Folland showed \[3\] Proposition 3.14] that

\[
\| \mathcal{R}_p^{i\tau} \|_{\mathcal{L}(L^p)} \leq C_p |\Gamma(1 - \tau)|^{-1} \quad \text{and} \quad \| (I + \mathcal{R}_p)^{i\tau} \|_{\mathcal{L}(L^p)} \leq C_p |\Gamma(1 - \tau)|^{-1},
\]

with \( C_p \) independent of \( \tau \in \mathbb{R} \). However his proof uses heavily the fact that the heat semigroup \( \{ e^{t\mathcal{L}} \}_{t>0} = \{ e^{-t\mathcal{R}} \}_{t>0} \) is a strongly continuous semigroup of contractions preserving
positivity, see Remark 2.10. This cannot be adapted in a simple way to the case of a general Rockland operator.

We will not pursue the question of improving the bounds for \( \|\mathcal{R}_p^{i\tau}\|_{L^p(L^p)} \) and \( \|(I + \mathcal{R}_p)^{i\tau}\|_{L^p(L^p)} \). Indeed we will only need some bounds for \( \|(I + \mathcal{R}_p)^{i\tau}\|_{L^p(L^p)} \) to show the property of interpolation between Sobolev spaces (i.e. in the proof of Theorem 4.8), and the bounds given in Theorem 3.5 and later in Corollary 3.11 will be sufficient for our purpose.

3.3. Riesz and Bessel potentials. In the next corollary, we proceed as in the proof of Theorem 3.5 (5) to realise \( \mathcal{R}^{-a/\nu}_p \) as a convolution operator with a homogeneous kernel smooth away from the origin for certain values of \( a \). We also consider the left-invariant (but non-homogeneous) operator \( (I + \mathcal{R})^{-a/\nu}_p \).

Definition 3.9. Mimicking the usual terminology in the Euclidean setting, we call the operators \( \mathcal{R}^{-a/\nu}_p \) for \( \{a \in \mathbb{C}, 0 < \text{Re} a < Q\} \) and \( (I + \mathcal{R})^{-a/\nu}_p \) for \( a \in \mathbb{C}_+ \), the Riesz potential and the Bessel potential, respectively. In the sequel we will denote their kernels by \( I_a \) and \( B_a \), respectively, as defined in the following:

Corollary 3.10. We keep the setting and notation of Theorem 3.3.

(i) Let \( a \in \mathbb{C} \) with \( 0 < \text{Re} a < Q \). The integral

\[
I_a(x) := \frac{1}{\Gamma(a/\nu)} \int_0^\infty t^{\frac{2}{\nu}-1}h_t(x)dt,
\]

converges absolutely for every \( x \neq 0 \). This defines a distribution \( I_a \) which is a kernel of type \( a \), that is, smooth away from the origin and \((a - Q)\)-homogeneous.

For any \( p \in (1, \infty) \), if \( \phi \in \mathcal{S}(G) \) or, more generally, if \( \phi \in L^q(G) \cap L^p(G) \) where \( q \in [1, \infty) \) is given by \( \frac{1}{q} - \frac{1}{p} = \frac{\text{Re} a}{Q} \), then

\[
\phi \in \text{Dom}(\mathcal{R}^{-a/\nu}_p) \quad \text{and} \quad \mathcal{R}^{-a/\nu}_p \phi = \phi \ast I_a \in L^p(G).
\]

(ii) Let \( a \in \mathbb{C}_+ \). The integral

\[
B_a(x) := \frac{1}{\Gamma(a/\nu)} \int_0^\infty t^{\frac{2}{\nu}-1}e^{-t}h_t(x)dt,
\]

converges absolutely for every \( x \neq 0 \). The function \( B_a \) is always smooth away from 0 and integrable on \( G \). If \( \text{Re} a > Q/2 \), then \( B_a \in L^2(G) \).

For each \( a \in \mathbb{C}_+ \), the operator \( (I + \mathcal{R})^{-a/\nu}_p \) is a bounded convolution operator on \( L^p(G) \) for \( p \in [1, \infty) \) or \( C_0(G) \) for \( p = \infty \), with the same (right convolution) kernel \( B_a \).

If \( a, b \in \mathbb{B}_+ \), then as integrable functions, we have \( B_a \ast B_b = B_{a+b} \).

Proof of Corollary 3.10. The absolute convergence and the smoothness of \( I_a \) and \( B_a \) follow from the estimates in (2.15).
For the homogeneity of $\mathcal{I}_a$, we use (2.10) and the change of variable $s = r^{-\nu}t$, to get
\[
\mathcal{I}_a(rx) = \frac{1}{\Gamma(a/\nu)} \int_0^\infty t^{\frac{a}{\nu}-1} h_t(rx) dt = \frac{1}{\Gamma(a/\nu)} \int_0^\infty (r^{\nu} s)^{\frac{a}{\nu}-1} r^{-Q} h_s(x) r^{\nu} ds = r^{a-Q} \mathcal{I}_a(x).
\]

By Theorem 2.4, the operator $\mathcal{S}(G) \ni \phi \mapsto \phi * \mathcal{I}_a$ is homogeneous of degree $-a$, and admits a bounded extension $L^p(G) \to L^p(G)$ when $\frac{1}{p} - \frac{1}{q} = \frac{\Re(a)}{Q}$. The rest of Part (i) follows from Theorem 3.5 together with Lemma 3.7.

By Theorem 2.9, $\int_G |h_t| = 1$ for all $t > 0$, so
\[
\int_G |B_a(x)| dx \leq \frac{1}{|\Gamma(a/\nu)|} \int_0^\infty t^{\frac{a}{\nu}-1} e^{-t} \int_G |h_t(x)| dx dt = \frac{\Gamma(\Re(a))}{|\Gamma(a/\nu)|},
\]
and $B_a$ is integrable. By Theorem 3.5 Part (i), the integrable function $B_a$ is the convolution kernel of $(I + \mathcal{R})^{-a/\nu}$.

Let us show the square integrability of $B_a$. We assume $\Re a > 0$. We compute for any $R > 0$:
\[
\Gamma(a/\nu)^2 \int_{|x| < R} |B_a(x)|^2 dx = \int_{|x| < R} B_a(x) \overline{B_a(x)} dx = \int_{|x| < R} \int_0^\infty t^{\frac{a}{\nu}-1} e^{-t} h_t(x) dt \int_0^\infty s^{\frac{a}{\nu}-1} e^{-s} \overline{h_s(x)} ds dx
\]
\[
= \int_0^\infty \int_0^\infty (st)^{\frac{a}{\nu}-1} e^{-(t+s)} \int_{|x| < R} h_t(x) \overline{h_s(x)} dx dt ds.
\]
From the properties of the heat kernel (see (2.11) and (2.9)) we see that
\[
\int_{|x| < R} h_t(x) \overline{h_s(x)} dx = \int_{|x| < R} h_t(x) h_s(x^{-1}) dx \xrightarrow{R \to \infty} h_t * h_s(0),
\]
and $h_t * h_s(0) = h_{t+s}(0) = (t+s)^{-\frac{a}{\nu}} h_1(0)$.

Therefore,
\[
\int_G |B_a(x)|^2 dx = \frac{h_1(0)}{\Gamma(a/\nu)^2} \int_0^\infty \int_0^\infty (st)^{\frac{a}{\nu}-1} e^{-(t+s)} (t+s)^{-\frac{a}{\nu}} dt ds
\]
\[
= \frac{h_1(0)}{\Gamma(a/\nu)^2} \int_0^1 \int_{s'} (s'(1-s'))^{\frac{a}{\nu}-1} ds' \int_{u=0}^\infty e^{-u} u^{2(\frac{a}{\nu}-1)-\frac{a}{\nu}+1} du,
\]
after the change of variables $u = s + t$ and $s' = s/u$. The integrals over $s'$ and $u$ converge when $\Re a > Q/2$. Thus $B_a$ is square integrable under this condition. The rest of the proof of Corollary 3.10 follows easily from the properties of the fractional powers of $I + \mathcal{R}$. □
Corollary 3.11. We keep the notation of Corollary 3.10. For any \( a \in \mathbb{C}_+ \), the operator norm of \( (I + R_p)^{-\frac{a}{\nu \mathcal{R}}} \) on \( L^p(G) \) if \( p \in [1, \infty) \) or \( C_0(G) \) if \( p = \infty \) is bounded by

\[
\| (I + R_p)^{-\frac{a}{\nu \mathcal{R}}} \|_{L^p} \leq \| B_a \|_1 \leq \Gamma \left( \frac{-\text{Re} a}{\nu \mathcal{R}} \right) \left| \Gamma \left( -\frac{a}{\nu \mathcal{R}} \right) \right|^{-1}.
\]

For any (fixed) \( a \leq 0 \) and \( p \in (1, \infty) \), the following quantity is finite:

\[
\sup_{y \in \mathbb{R}} e^{-3|y|} \ln \| (I + R_p)^{-\frac{a+i\nu}{\nu \mathcal{R}}} \|_{L^p}.
\]

Proof of Corollary 3.11. The first part is a direct consequence of Corollary 3.10 (ii) and its proof. If \( a > 0 \), the second part follows from the first together with Sterling’s estimates. If \( a = 0 \), it is a consequence of the exponential bounds for the operator norms obtained in Theorem 3.5 (6). \( \square \)

We now state the following technical lemma and its corollaries which will be useful in the sequel.

Lemma 3.12. We keep the notation of Corollary 3.10.

(i) For any \( \phi \in \mathcal{S}(G) \) and \( a \in \mathbb{C}_+ \), the function \( \phi \ast B_a \) is Schwartz.

(ii) Let \( a \in \mathbb{C} \) and \( \phi \in \mathcal{S}(G) \). Then \( (I + R_p)^a \phi \) does not depend on \( p \in [1, \infty) \cup \{\infty\} \). If \( a \in \mathbb{N} \), \( (I + R_p)^a \phi \) coincides with \( (I + R)^a \phi \). If \( a \in \mathbb{C}_+ \), we have

\[
(I + R_p)^a (\phi \ast B_{av}) = ((I + R_p)^a \phi) \ast B_{av} = \phi \quad (p \in [1, \infty) \cup \{\infty\}).
\]

(iii) For any \( N \in \mathbb{N} \), \( (I + R)^N(\mathcal{S}(G)) = \mathcal{S}(G) \).

Proof. Let \( |\cdot| \) be a homogeneous pseudo-norm on \( G \) and \( N \in \mathbb{N} \). We see that

\[
\int_G |x|^N |B_a(x)| \, dx \leq \frac{1}{|\Gamma\left(\frac{N}{2}\right)|} \int_0^\infty t^{\frac{\text{Re} a - N}{\nu \mathcal{R}}} e^{-t} \int_G |x|^N |h_t(x)| \, dx \, dt,
\]

and using the homogeneity of the heat kernel (see (2.14)) and the change of variables \( y = t^{-\frac{1}{\nu}} x \), we get

\[
\int_G |x|^N |h_t(x)| \, dx = \int_G |t^{\frac{1}{2}} y|^N |h_1(y)| \, dy = c_N t^{\frac{N}{2}},
\]

where \( c_N = \| |y|^N h_1(y) \|_{L^1(dy)} \) is a finite constant since \( h_1 \in \mathcal{S}(G) \). Thus,

\[
\int_G |x|^N |B_a(x)| \, dx \leq \frac{c_N}{|\Gamma\left(\frac{N}{2}\right)|} \int_0^\infty t^{\frac{\text{Re} a - \frac{N}{2}}{\nu \mathcal{R}}} e^{-t} \, dt < \infty,
\]

and \( x \mapsto |x|^N B_a(x) \) is integrable.
Let $C_\circ \geq 1$ denote the constant in the triangle inequality for $|\cdot|$ (see Proposition 2.1). Let also $\phi \in \mathcal{S}(G)$. We have for any $N \in \mathbb{N}$ and $\alpha \in \mathbb{N}_0^n$:

$$\left(1 + |x| \right)^N \left| \tilde{X}[\phi \ast B_\alpha](x) \right| = \left(1 + |x| \right)^N \left| \tilde{X}(\phi \ast B_\alpha)(x) \right|$$

$$\leq \left(1 + |x| \right)^N \left| \tilde{X}(\phi) \right| * |B_\alpha| (x)$$

$$\leq C_\circ N \left\| (1 + |\cdot|)^N \tilde{X}(\phi) \right\|_\infty \left\| (1 + |\cdot|)^N B_\alpha \right\|_{L^1(G)}.$$

This shows that that $\phi \ast B_\alpha \in \mathcal{S}(G)$ (for a description of the Schwartz class, see [1] Chapter 1 D) and Part (i) is proved.

Part (ii) follows easily from Theorem 3.5 and Corollary 3.10.

Let us prove Part (iii). By Theorem 3.3 (iv), we have the inclusion $(I+\mathcal{R})^N(S(G)) \subseteq S(G)$. The reverse inclusion $S(G) \subseteq (I+\mathcal{R})^N(S(G))$ follows from (3.8) and Theorem 3.3 (iv). So for any $N \in \mathbb{N}$, $S(G)$ is included in $\text{Dom} [(I+\mathcal{R})^N] \cap \text{Range} [(I+\mathcal{R})^N]$ and we can apply the analyticity results of Theorem 3.5: the function $a \mapsto (I+\mathcal{R}_p)^a \phi$ is holomorphic in $\{a \in \mathbb{C} : -N < \text{Re} a < N\}$. We observe that by Corollary 3.10 (ii), if $-N < \text{Re} a < 0$, all the functions $(I+\mathcal{R}_p)^a \phi$ coincide with $\phi \ast B_\alpha \nu$ for any $p \in [1, \infty) \cup \{\infty_0\}$. This shows that for each $a \in \mathbb{C}$ fixed, $(I+\mathcal{R}_p)^a \phi$ is independent of $p$. This concludes the proof of Lemma 3.12.

\[\square\]

4. Sobolev spaces on graded groups

In this section we define the Sobolev spaces associated to a positive Rockland operator $\mathcal{R}$ and show that they satisfy similar properties to the Euclidean Sobolev spaces. We will show that the constructed spaces are actually independent of the choice of a positive Rockland operator $\mathcal{R}$ on a graded group with which we start our construction.

4.1. Definition and first properties of Sobolev spaces. We first need the following lemma:

**Lemma 4.1.** We keep the notation of Theorem 3.5. For any $s \in \mathbb{R}$ and $p \in [1, \infty) \cup \{\infty_0\}$, the domain of the operator $(I+\mathcal{R}_p)^s$ contains $S(G)$, and the map

$$f \mapsto \|(I+\mathcal{R}_p)^s f\|_{L^p(G)}$$

defines a norm on $S(G)$. We denote it by

$$\|f\|_{L^p_s(G)} := \|(I+\mathcal{R}_p)^s f\|_{L^p(G)}.$$

Moreover, any sequence in $S(G)$ which is Cauchy for $\|\cdot\|_{L^p_s(G)}$ is convergent in $S'(G)$.
We have allowed ourselves to write \( \| \cdot \|_{L^\infty(G)} = \| \cdot \|_{L^\infty_c(G)} \) for the supremum norm. We may also write \( \| \cdot \|_\infty \) or \( \| \cdot \|_{\infty_c} \).

**Proof.** The domain of \((I + R_p)^{\frac{\nu}{p}}\) contains \(S(G)\):

- by Theorem 3.3 Part (2) for \( s > 0 \),
- by Corollary 3.10 (ii) for \( s < 0 \) and,
- for \( s = 0 \), since \((I + R_p)^{\frac{\nu}{p}} = I\).

Since the operator \((I + R_p)^{\frac{\nu}{p}}\) is linear, it is easy to check that the map \( f \mapsto \| (I + R_p)^{\frac{\nu}{p}} f \|_p \) is non-negative and satisfies the triangle inequality. Since \((I + R_p)^{s/\nu}\) is injective by Theorem 3.5 Part (1), we have that \( \| f \|_{L^p_c(G)} = 0 \) implies \( f = 0 \).

Clearly \( \| \cdot \|_{L^p_c(G)} = \| \cdot \|_p \), so in the case of \( s = 0 \) a Cauchy sequence of Schwartz functions converges in \( L^p \)-norm, thus also in \( S'(G) \).

Let us assume \( s > 0 \). By Corollary 3.10 (ii), the operator \((I + R_p)^{-\frac{\nu}{p}}\) is bounded on \( L^p(G) \). Hence we have \( \| \cdot \|_{L^p(G)} \leq C \| \cdot \|_{L^p_c(G)} \) on \( S(G) \). Consequently a \( \| \cdot \|_{L^p_c(G)} \)-Cauchy sequence of Schwartz functions converges in \( L^p \)-norm thus in \( S'(G) \).

Now let us assume \( s < 0 \). Let \( \{ f_\ell \}_{\ell \in \mathbb{N}} \) be a sequence of Schwartz functions which is Cauchy for the norm \( \| \cdot \|_{L^p_c(G)} \). By (3.8) we have \( f_\ell = ((I + R_p)^{\frac{\nu}{p}} f_\ell) * B_s \). Furthermore, if \( \phi \in S(G) \) then using (2.1) and (2.11), we have

\[
\begin{align*}
\int_G f_\ell(x) \phi(x) dx &= \int_G ((I + R_p)^{\frac{\nu}{p}} f_\ell) (x) (\phi * B_s) (x) dx.
\end{align*}
\]

By assumption the sequence \( \{ (I + R_p)^{\frac{\nu}{p}} f_\ell \}_{\ell \in \mathbb{N}} \) is \( \| \cdot \|_{L^p(G)} \)-Cauchy thus convergent in \( L^p(G) \). By Lemma 3.12 \( \phi * B_s \in S(G) \). Therefore, the right hand-side of (4.1) is convergent as \( \ell \to \infty \). Hence the scalar sequence \( \langle f_\ell, \phi \rangle \) converges for any \( \phi \in S(G) \). This shows that the sequence \( \{ f_\ell \} \) converges in \( S'(G) \). \( \square \)

Lemma 4.1 allows us to define the Sobolev spaces:

**Definition 4.2.** Let \( \mathcal{R} \) be a positive Rockland operator on \( G \). We consider its \( L^p \)-analogue \( \mathcal{R}_p \) and the powers of \((I + \mathcal{R}_p)^{\alpha}\) as defined in Theorems 3.3 and 3.5. Let \( s \in \mathbb{R} \).

If \( p \in [1, \infty) \), the **Sobolev space** \( L_{s,\mathcal{R}}^p(G) \) is the subspace of \( S'(G) \) obtained by completion of \( S(G) \) with respect to the **Sobolev norm**

\[
\| f \|_{L_{s,\mathcal{R}}^p(G)} := \| (I + \mathcal{R}_p)^{\frac{s}{p}} f \|_{L^p(G)}, \quad f \in S(G).
\]

If \( p = \infty \), the **Sobolev space** \( L_{s,\mathcal{R}}^\infty(G) \) is the subspace of \( S'(G) \) obtained by completion of \( S(G) \) with respect to the **Sobolev norm**

\[
\| f \|_{L_{s,\mathcal{R}}^\infty(G)} := \| (I + \mathcal{R}_\infty)^{\frac{s}{\infty}} f \|_{L^\infty(G)}, \quad f \in S(G).
\]

When the Rockland operator \( \mathcal{R} \) is fixed, we may allow ourselves to drop the index \( \mathcal{R} \) in \( L_{s,\mathcal{R}}^p(G) = L_s^p(G) \) to simplify the notation.
We will see later that the Sobolev spaces do not depend on the Rockland operator \( \mathcal{R} \), see Theorem 4.11.

By construction the Sobolev space \( L^p_s(G) \) endowed with the Sobolev norm is a Banach space which contains \( \mathcal{S}(G) \) as a dense subspace and is included in \( \mathcal{S}'(G) \). The Sobolev spaces share many properties with their Euclidean counterparts.

**Theorem 4.3.** Let \( \mathcal{R} \) be a positive Rockland operator on \( G \). We consider the associated Sobolev spaces \( L^p_s(G) \) for \( p \in [1, \infty) \cup \{ \infty \} \) and \( s \in \mathbb{R} \).

1. If \( s = 0 \), then \( L^p_0(G) = L^p(G) \) for \( p \in [1, \infty) \) with \( \| \cdot \|_{L^p_0(G)} = \| \cdot \|_{L^p(G)} \), and \( L^\infty_0(G) = C_0(G) \) with \( \| \cdot \|_{L^\infty_0(G)} = \| \cdot \|_{L^\infty(G)} \).

2. If \( s > 0 \), then for any \( a \in \mathbb{C} \) with \( \Re a = s \), we have

\[
L^p_s(G) = \text{Dom} \left( [I + \mathcal{R}_p]^\frac{s}{p} \right) = \text{Dom}(\mathcal{R}_p^\frac{s}{p}) \subset L^p(G),
\]

and the following norms are equivalent to \( \| \cdot \|_{L^p_s(G)} \):

\[
f \mapsto \| f \|_{L^p(G)} + \| (I + \mathcal{R}_p)^{-\frac{s}{p}} f \|_{L^p(G)}, \quad f \mapsto \| f \|_{L^p(G)} + \| \mathcal{R}_p^\frac{s}{p} f \|_{L^p(G)}.
\]

3. Let \( s \in \mathbb{R} \) and \( f \in \mathcal{S}'(G) \).

   - Given \( p \in (1, \infty) \), then \( f \in L^p_s(G) \) if and only if \( (I + \mathcal{R}_p)^{s/p} f \in L^p(G) \) in the sense that the linear mapping \( \mathcal{S}(G) \ni \phi \mapsto \langle f, (I + \mathcal{R}_p)^{s/p} \phi \rangle \) extends to a bounded functional on \( L^p(G) \) where \( p' \) is the conjugate exponent of \( p \).
   - \( f \in L^1_s(G) \) if and only if \( (I + \mathcal{R}_1)^{s/p} f \in L^1(G) \) in the sense that the linear mapping \( \mathcal{S}(G) \ni \phi \mapsto \langle f, (I + \mathcal{R}_1)^{s/p} \phi \rangle \) extends to a bounded functional on \( C_0(G) \) and is realised as a measure given by an integrable function.
   - \( f \in L^\infty_s(G) \) if and only if \( (I + \mathcal{R}_1)^{s/p} f \in C_0(G) \) in the sense that the linear mapping \( \mathcal{S}(G) \ni \phi \mapsto \langle f, (I + \mathcal{R}_1)^{s/p} \phi \rangle \) extends to a bounded functional on \( L^1(G) \) and is realised as integration against function in \( C_0(G) \).

4. If \( a, b \in \mathbb{R} \) with \( a < b \) and \( p \in [1, \infty) \cup \{ \infty \} \), then the following continuous strict inclusions hold

\[
\mathcal{S}(G) \subset L^p_0(G) \subset L^p_s(G) \subset \mathcal{S}'(G),
\]

and an equivalent norm for \( L^p_s(G) \) is

\[
L^p_s(G) \ni f \mapsto \| f \|_{L^p_s(G)} + \| \mathcal{R}^{\frac{b-a}{p}} f \|_{L^p_s(G)}.
\]

From now on, we will often use the notation \( L^p_0(G) \) since this allows us not to distinguish between the cases \( L^p_0(G) = L^p(G) \) when \( p \in [1, \infty) \) and \( L^p_0(G) = C_0(G) \) when \( p = \infty \).

**Proof of Theorem 4.3.** Part (1) is true since \( (I + \mathcal{R}_p)^\frac{s}{p} = I \).

Let us prove Part (2). So let \( s > 0 \). Clearly \( L^p_s(G) \) coincides with the domain of the unbounded operator \( (I + \mathcal{R}_p)^\frac{s}{p} \) (see Theorem 3.5 [2]) hence it is a proper subspace of \( L^p(G) \). As the operator \( (I + \mathcal{R}_p)^{-\frac{s}{p}} \) is bounded on \( L^p(G) \), we have \( \| \cdot \|_{L^p(G)} \leq C \| \cdot \|_{L^p_s(G)} \) on \( L^p_s(G) \).
So \( \| \cdot \|_{L^p(G)} + \| \cdot \|_{L^p_s(G)} \) is a norm on \( L^p_s(G) \) which is equivalent to the Sobolev norm. By Theorem 3.5, the operators \( \mathcal{R}_p^\delta \) and \((1 + \mathcal{R}_p)^{\frac{b-a}{2}}\) share the same domain. Hence Part (2) follows from general functional analysis, especially the closed graph theorem.

Part (3) follows from Part (2) in the case \( s \geq 0 \). We now consider the case \( s < 0 \). By Lemma 3.12 and Corollary 3.10, the mapping

\[ T_{s,p',f} : \mathcal{S}(G) \ni \phi \mapsto \langle f, (1 + \mathcal{R}_{p'})^{s/\nu} \phi \rangle = \langle f, \phi \ast \overline{\mathcal{B}}_{-s} \rangle \]

is well defined for any \( f \in \mathcal{S}'(G) \). If \( T_{s,p',f} \) admits a bounded extension to a functional on \( L^p_s(G) \), then we denote this extension \( \tilde{T}_{s,p',f} \) and we have \( \| \tilde{T}_{s,p',f} \|_{\mathcal{L}(L^p')} = \| f \|_{L^p_s(G)} \). This is certainly so if \( f \in \mathcal{S}(G) \). The proof of Part (3) follows from the following observation: a sequence \( \{ f_k \} \in \mathbb{N} \) of Schwartz functions is convergent for the Sobolev norm \( \| \cdot \|_{L^p_s(G)} \) if and only if \( \{ \tilde{T}_{s,p',f_k} \} \) is convergent in \( L^p_s(G) \).

Let us show Part (4). Let \( a \leq b \) and \( p \in [1, \infty) \cup \{ \infty \} \). Theorem 3.5 implies that for any \( f \in \mathcal{S}(G) \) we have

\[ \| f \|_{L^p_b(G)} \leq \|(1 + \mathcal{R}_p)^{\frac{b-a}{2}} \mathcal{L}(L^p_b)\| f \|_{L^p_a}. \]

By density of \( \mathcal{S}(G) \), this yields the continuous inclusion \( L^p_b \subset L^p_a \). If \( a < b \), we also have

\[ \| f \|_{L^p_b(G)} = \|(1 + \mathcal{R}_p)^{\frac{b-a}{2}} f \|_{L^p_b(G)} \leq \|(1 + \mathcal{R}_p)^{\frac{b-a}{2}} f \|_{L^p_b(G)} + \| \mathcal{R}_p^{b/a} (1 + \mathcal{R}_p)^{\frac{a-b}{2}} f \|_{L^p_b(G)} \]

by Part (2) above for any \( f \in \mathcal{S}(G) \). By Theorem 3.5 (7), we can commute the operators \( \mathcal{R}_p^{b/a} \) and \((1 + \mathcal{R}_p)^{\frac{a-b}{2}}\) in this last expression. This shows that the Sobolev norm is equivalent to \( \| \cdot \|_{L^p_b(G)} \cong \| \cdot \|_{L^p_a(G)} + \| \mathcal{R}_p^{b/a} \| \cdot \| \mathcal{L}_{b/a}(G) \). Since the operator \( \mathcal{R}_p^{b/a} \) is unbounded, this also implies the strict inclusions given in Part (4). This concludes the proof of this part and of the whole theorem. \( \square \)

Theorem 4.3 has the following corollaries. The first two are easy consequences of Part (3) left to the reader.

Corollary 4.4. We keep the setting and notation of Theorem 4.3. Let \( s < 0 \) and \( p \in [1, \infty) \cup \{ \infty \} \). Let \( f \in \mathcal{S}'(G) \).

The tempered distribution \( f \) is in \( L^p_s(G) \) if and only if the mapping \( \phi \in \mathcal{S}(G) \mapsto \langle f, \phi \ast \overline{\mathcal{B}}_{-s} \rangle \) extends to a bounded linear functional on \( L^p_s(G) \) with the additional property that

- for \( p = 1 \), this functional on \( C_o(G) \) is realised as a measure given by an integrable function,
- if \( p = \infty \), this functional on \( L^1(G) \) is realised by integration against a function in \( C_o(G) \).

Corollary 4.5. Let \( \mathcal{R} \) be a positive Rockland operator on a graded Lie group \( G \). We consider the associated Sobolev spaces \( L^p_{s,\mathcal{R}}(G) \). If \( s \in \mathbb{R} \) and \( p \in (1, \infty) \), the dual space of \( L^p_{s,\mathcal{R}}(G) \) is
isomorphic to $L^{p'}_{-s, \overline{R}(G)}$ via the distributional duality, where $p'$ is the conjugate exponent of $p$.

Corollary 4.5 will be improved in Proposition 4.13 once we show (see Theorem 4.11) that Sobolev spaces are indeed independent of the considered Rockland operator.

**Corollary 4.6.** We keep the setting and notation of Theorem 4.3. Let $s \in \mathbb{R}$ and $p \in [1, \infty) \cup \{\infty\}$. Then $\mathcal{D}(G)$ is dense in $L^p_s(G)$.

**Proof of Corollary 4.6.** This is certainly true for $s \geq 0$ (see the proof of Parts (1) and (2) of Theorem 4.3). For $s < 0$, it suffices to proceed as in the last part of the proof of Part (3) with a sequence of functions $f_\ell \in \mathcal{D}(G)$. □

In the next statement, we show how to produce functions and converging sequences in Sobolev spaces using the convolution:

**Proposition 4.7.** We keep the setting and notation of Theorem 4.3. Here $a \in \mathbb{R}$ and $p \in [1, \infty) \cup \{\infty\}$.

(i) If $f \in L^p_0(G)$ and $\phi \in \mathcal{S}(G)$, then $f \ast \phi \in L^p_a(G)$ for any $a$ and $p$.

(ii) If $f \in L^p_a(G)$ and $\psi \in \mathcal{S}(G)$, then

\[
(I + \mathcal{R}_p)^{\frac{a}{2}}(\psi \ast f) = \psi \ast ((I + \mathcal{R}_p)^{\frac{a}{2}}f),
\]

and $\psi \ast f \in L^p_a(G)$ with $\|\psi \ast f\|_{L^p_a(G)} \leq \|\psi\|_{L^1(G)}\|f\|_{L^p_a(G)}$. Furthermore, writing $\psi_\varepsilon(x) := \varepsilon^{-\nu}\psi(\varepsilon^{-1}x)$ for each $\varepsilon > 0$, then $\{\psi_\varepsilon \ast f\}$ converges to $f$ in $L^p_a(G)$ as $\varepsilon \to 0$.

**Proof of Proposition 4.7.** Let us prove Part (i). Here $f \in L^p_0(G)$. By density of $\mathcal{S}(G)$ in $L^p_0(G)$, we can find a sequence of Schwartz functions $\{f_\ell\}$ converging to $f$ in $L^p_0$-norm. Then $f_\ell \ast \phi \in \mathcal{S}(G)$ and for any $N \in \mathbb{N}$,

\[
\mathcal{R}^N(f_\ell \ast \phi) = f_\ell \ast \mathcal{R}^N\phi \longrightarrow f \ast \mathcal{R}^N\phi \quad \text{in} \quad L^p_0(G),
\]

thus $\mathcal{R}^N_p(f \ast \phi) = f \ast \mathcal{R}^N_p\phi \in L^p_0(G)$ and

\[
\|f \ast \phi\|_{L^p_0(G)} + \|\mathcal{R}^N_p(f \ast \phi)\|_{L^p_0(G)} < \infty.
\]

By Theorem 4.3 (4), this shows that $f \ast \phi$ is in $L^p_{\nu_N}$ for any $N \in \mathbb{N}$, hence in any $p$-Sobolev spaces (cf. Theorem 4.3 (4)). This proves (i).

Let us prove Part (ii). We observe that both sides of Formula (4.2) always make sense as convolutions of a Schwartz function with a tempered distribution. Formula (4.2) is clearly true if $a < 0$ by Corollary 3.10 (ii) since then the $(I + \mathcal{R}_p)^{\frac{a}{2}}$ is a convolution operator. Consequently (4.2) is true also for any $f, \psi \in \mathcal{S}(G)$ and $a \in \mathbb{R}$ by the analyticity result of
Theorem 3.5 and Lemma 3.12. Using this result for Schwartz functions yields that Equality (4.2) holds as distributions for any \( f \in L^p(G) \), \( \phi \in \mathcal{S}(G) \), and \( a \in \mathbb{R} \), since we have

\[
\langle (I + \mathcal{R}_p)^{\frac{p}{2}} (\psi \ast f), \phi \rangle = \langle \psi \ast f, (I + \bar{\mathcal{R}}_p)^{\frac{p}{2}} \phi \rangle = \langle f, (I + \bar{\mathcal{R}}_p)^{\frac{p}{2}} (\psi \ast \phi) \rangle = \langle (I + \mathcal{R}_p)^{\frac{p}{2}} f, \psi \ast \phi \rangle.
\]

Taking the \( L^p \)-norm on both sides of Equality (4.2) yields

\[
\| (I + \mathcal{R}_p)^{\frac{p}{2}} (\psi \ast f) \|_p = \| \psi \ast ((I + \mathcal{R}_p)^{\frac{p}{2}} f) \|_p \leq \| \psi \|_1 \| (I + \mathcal{R}_p)^{\frac{p}{2}} f \|_p.
\]

Hence \( \psi \ast f \in L^p_a(G) \) with \( L^p_a \)-norm \( \leq \| \psi \|_1 \| f \|_{L^p_a(G)} \). Moreover, by Lemma 2.7,

\[
\| \psi \ast f - f \|_{L^p_a(G)} = \| (I + \mathcal{R}_p)^{\frac{p}{2}} (\psi \ast f - f) \|_p = \| \psi \ast ((I + \mathcal{R}_p)^{\frac{p}{2}} f) - (I + \mathcal{R}_p)^{\frac{p}{2}} f \|_p \to 0, 
\]

that is, \( \{ \psi \ast f \} \) converges to \( f \) in \( L^p_a(G) \) as \( \epsilon \to 0 \). This proves (ii). \( \square \)

We note that, in general, keeping the notation of Proposition 4.7 (ii), it is not possible to prove that \( \{ f \ast \psi_\epsilon \} \) converges to \( f \) in \( L^p_a(G) \) as \( \epsilon \to 0 \) for any sequence \( \{ \psi_\epsilon \}_{\epsilon > 0} \). We need to know that \( \{ \psi_\epsilon \}_{\epsilon > 0} \) yields an \( L^p \) approximation of the identity, that is, \( f \ast \psi_\epsilon \to f \) in \( L^p \) as \( \epsilon \to 0 \) for any \( f \in L^p(G) \).

4.2. Interpolation between Sobolev spaces. In this section, we prove that interpolation between Sobolev spaces \( L^p_a(G) \) works in the same way as its Euclidean counterpart.

**Theorem 4.8.** Let \( \mathcal{R} \) and \( \mathcal{Q} \) be two positive Rockland operators on two graded Lie groups \( G \) and \( F \). We consider their associated Sobolev spaces \( L^p_a(G) \) and \( L^q_b(F) \). Let \( p_0, p_1, q_0, q_1 \in (1, \infty) \) and real numbers \( a_0, a_1, b_0, b_1 \).

We also consider a linear mapping \( T \) from \( L^{p_0}_{a_0}(G) + L^{p_1}_{a_1}(G) \) to locally integrable functions on \( F \). We assume that \( T \) maps \( L^{p_0}_{a_0}(G) \) and \( L^{p_1}_{a_1}(G) \) boundedly into \( L^{q_0}_{b_0}(F) \) and \( L^{q_1}_{b_1}(F) \), respectively.

Then \( T \) extends uniquely to a bounded mapping from \( L^p_{a_t}(G) \) to \( L^q_{b_t}(F) \) for \( t \in [0, 1] \) where \( a_t, b_t, p_t, q_t \) are defined by

\[
\left( a_t, b_t, \frac{1}{p_t}, \frac{1}{q_t} \right) = (1 - t) \left( a_0, b_0, \frac{1}{p_0}, \frac{1}{q_0} \right) + t \left( a_1, b_1, \frac{1}{p_1}, \frac{1}{q_1} \right).
\]

The idea of the proof is similar to the one of the Euclidean or stratified cases, see [3, Theorem 4.7], with some modifications since our estimates for \( \| (I + \mathcal{R})^\alpha \|_{L^p} \) are different to the ones obtained by Folland in [3]. For this, compare Corollary 3.11 in this monograph with [3, Proposition 4.3]. See also Remark 3.8.

**Proof of Theorem 4.8.** By duality (see Corollary 4.5) and up to a change of notation, it suffices to prove the case \( a_1 \geq a_0 \) and \( b_1 \leq b_0 \). The idea is to interpolate between the
operators formally given by
\begin{equation}
T_z = (I + Q)^{b_z / \nu_Q} T(I + R)^{-a_z / \nu_R},
\end{equation}
where \( \nu_R \) and \( \nu_Q \) denote the degrees of homogeneity of \( R \) and \( Q \) respectively and the complex numbers \( a_z \) and \( b_z \) are defined by
\[(a_z, b_z) := (a_1, b_1) + (1 - z)(a_0, b_0),\]
for \( z \) in the strip
\[S := \{ z \in \mathbb{C} : \Re z \in [0, 1] \}.
\]
In (4.3), we have abused the notation regarding the fractional powers of \( R_p \) and \( Q_q \) and removed \( p \) and \( q \). This is possible by Lemma 3.12 and density of the Schwartz space in each Sobolev space. Hence (4.3) makes sense.

By Lemma 3.12 for any \( \phi \in \mathcal{S}(G) \) and \( \psi \in \mathcal{S}(F) \), we have
\[
\langle T_z \phi, \psi \rangle = \langle T(I + R)^{-N - \frac{b_z}{\nu_R}} (I + R)^N \phi, (I + Q)^{-M + \frac{b_z}{\nu_Q}} (I + Q)^M \psi \rangle
\]
for any \( M, N \in \mathbb{Z} \). In particular for \( -M \) and \( -N \) large enough, Theorem 3.5 implies that \( S \ni z \mapsto \langle T_z \phi, \psi \rangle \) is analytic. With \( M = N \in \mathbb{N} \) the smallest integer with \( N > a_1, a_0, b_1, b_0 \), by Corollary 3.11 we get
\[
\|T_z\|_{\mathcal{L}(L^p_j, L^q_j)} \leq \Gamma \left( \frac{N - \Re z(a_1 - a_0)}{\nu_R} \right) \Gamma \left( \frac{N - \Re z(b_0 - b_1)}{\nu_Q} \right) \|T\|_{\mathcal{L}(L^p_1, L^{q_1}_1)} \|\phi\|_{L^p_N} \|\psi\|_{L^{q_j}_N}.
\]
Using Sterling’s estimates, we obtain
\[
\forall z = x + iy \in S \quad \ln |\langle T_z \phi, \psi \rangle| \leq \ln |y|(2|y| + O(\ln |y|))
\]
with the constant from the notation \( O \) depending on \( \phi, \psi, a_1, a_0, b_1, b_0 \).

The operator norms of \( T_z \) for \( z \) on the boundary of the strip, that is, \( z = j + iy, j = 0, 1, y \in \mathbb{R} \) may be easily estimated by:
\[
\|T_z\|_{\mathcal{L}(L^p_j, L^q_j)} \leq \|\left( I + Q_{q_j} \right)^{b_z/b_j} \|T\|_{\mathcal{L}(L^p_j, L^{q_j}_j)} \|\left( I + R_{p_j} \right)^{a_z/a_j} \|_{\mathcal{L}(L^p_j)}.
\]
And since \( \Re (b_z - b_j) \leq 0 \) and \( \Re (a_z - a_j) \leq 0 \), Corollary 3.11 then implies
\[
\sup_{y \in \mathbb{R}} e^{-3|y|} \ln \|T_{j+iy}\|_{\mathcal{L}(L^p_j, L^q_j)} < \infty, \quad j = 0, 1.
\]

The end of the proof is now classical. We fix a non-negative function \( \chi \in \mathcal{S}(G) \) with \( \int_G \chi = 1 \) and write \( \chi_\epsilon(x) := e^{-\epsilon Q}(\epsilon^{-1} x) \) for \( \epsilon > 0 \). If \( f \in \mathcal{B} \), one can show easily that \( f * \chi_\epsilon \in \mathcal{S}(\mathbb{R}^n) \) and we can define \( T_{z, \epsilon} f := T_z(f * \chi_\epsilon) \) for any \( \epsilon > 0, z \in S \). Clearly \( T_{z, \epsilon} \) satisfy the hypotheses of the Stein-Weiss interpolation theorem, see [21] ch. V §4. Thus for any \( t \in [0, 1] \), there exists a constant \( M_t > 0 \) independent of \( \epsilon \) such that \( \|T_{z, \epsilon} f\|_{q_t} \leq M_t \|f\|_{p_t} \) for any \( f \in \mathcal{B} \).
For $p \in (1, \infty)$, let $\mathcal{V}_p$ be the space of functions $\phi$ of the form $\phi = f \ast \chi_\epsilon$, with $f \in \mathcal{B}$ and $\epsilon > 0$, satisfying $\|f\|_p \leq 2 \|f \ast \chi_\epsilon\|_p$. It is easy to show that the space $\mathcal{V}_p$ contains $\mathcal{S}(G)$ and is dense in $L^p(G)$. We have obtained for any $t \in [0, 1]$ and $\phi = f \ast \chi_\epsilon \in \mathcal{V}_p$, that

$$\|T_t \phi\|_{q_t} = \|T_t \epsilon f\|_{q_t} \leq M_t \|f\|_{p_t} \leq 2M_t \|\phi\|_{p_t}.$$ 
This shows that $T_t$ extends to a bounded operator from $L^{p_t}(G)$ to $L^{p_t}(G)$. □

4.3. Differential operators acting on Sobolev spaces. In this section we study how differential operators act on Sobolev spaces.

**Theorem 4.9.** Let $T$ be any homogeneous left-invariant differential operator of homogeneous degree $\nu_T > 0$. Then for every $p \in (1, \infty)$, the operators $TR_p^{-\nu_T}$ and $R_p^{-\nu_T}T$ are of type $0$ and, consequently, extend to continuous operators on $L^p(G)$.

Furthermore, $T$ maps continuously $L^p_{\nu + \nu_T}(G)$ to $L^p_{s}(G)$ for every $s \in \mathbb{R}$, and if $s > 0$, there exists a constant $C = C_{s,T} > 0$ such that

$$\forall \phi \in \mathcal{S}(G) \quad \|R_{p}^{-\nu_T} T \phi\|_p \leq C \|R_{p}^{-\nu_T} \phi\|_p.$$ 

**Proof.** Let us fix $\alpha \in \mathbb{N}_0^\nu \setminus \{0\}$. Proceeding as in the proof of Corollary 3.10, we can show easily that, for any $a \in \mathbb{C}$ with $\text{Re } a - Q - [\alpha] < 0$, the integral

$$\mathcal{I}_{a,\alpha}(x) := \frac{1}{\Gamma(a/\nu)} \int_0^\infty t^{\frac{a}{\nu} - 1} X^\alpha h_t(x)dt,$$
converges absolutely for $x \neq 0$, and in this case it defines a function $\mathcal{I}_{a,\alpha}$ which is smooth away from the origin and $\text{Re } (a - Q - [\alpha])$-homogeneous. Furthermore, $\mathcal{I}_{a,\alpha} = X^\alpha \mathcal{I}_a$ if $a \in (0, Q)$.

Since $\mathcal{I}_a$ is a distribution, this shows that in this case $\mathcal{I}_{a,\alpha}$ is also a distribution. Hence if $\text{Re } a \in (0, Q)$ and $\text{Re } a - Q - [\alpha] < 0$ then $\mathcal{I}_{a,\alpha}$ is a kernel of type $a - [\alpha]$.

Let $N = \lfloor \frac{Q+1}{\nu} \rfloor$. We also fix a function $\psi \in D(G)$ with $\int_G \psi = 1$. We set $\psi_t(x) := t^{-Q} \psi(t^{-1}x)$. For any $\phi \in \mathcal{D}^N(\mathcal{S}(G))$, the map $a \mapsto (R_p^{-\nu_T} \phi) \ast X^\alpha \psi_t$ is holomorphic on $\{|\text{Re } a| < N\}$. On $\{\text{Re } a \in (0, Q)\}$ it coincides with $a \mapsto (\phi \ast \mathcal{I}_a) \ast \tilde{X}^\alpha \psi_t$. But we see that

$$(\phi \ast \mathcal{I}_a) \ast \tilde{X}^\alpha \psi_t = (X^\alpha (\phi \ast \mathcal{I}_a)) \ast \psi_t = (\phi \ast X^\alpha \mathcal{I}_a) \ast \psi_t = (\phi \ast X^\alpha \mathcal{I}_a,\alpha) \ast \psi_t,$$
and it is not difficult to check that $a \mapsto (\phi \ast \mathcal{I}_{a,\alpha}) \ast \psi_t$ is holomorphic on $\{0 < \text{Re } a < Q - \alpha\}$ and continuous on $\{\text{Re } a = Q - \alpha\}$. Therefore, we have obtained

$$(R_p^{-\nu_T} \phi) \ast \tilde{X}^\alpha \psi_t = (\phi \ast \mathcal{I}_{[\alpha],\alpha}) \ast \psi_t.$$ 

Letting $t \to 0$, we obtain that $X^\alpha R_p^{-[\alpha]}$ coincide with the convolution operator with the right-convolution kernel $\mathcal{I}_{[\alpha],\alpha}$, therefore it is an operator of type $0$. This is so for any $\alpha \in \mathbb{N}_0^\nu$. Consequently since any left-invariant $\nu_T$-homogeneous differential operator $T$ on $G$ is a linear combination of $X^\alpha$ with $[\alpha] = \nu_T$, $T R_p^{-[\alpha]}$ also admits a kernel of type $0$. Necessarily it is
also the case for its dual operator $R_p^{-\alpha} T$. This shows the first part of the statement for $R_p^{-\alpha} T$.

Now let us apply this to the operator $R^N T$ for $N \in \mathbb{N}_0$: the operator $R^N T R_p^{-\nu_T - N}$ extends to an $L^p(G)$-bounded operator for every $p \in (1, \infty)$. Since $R_p^{-\nu_T}$ is injective, we obtain

$$\forall \psi \in \mathcal{S}(G) \quad \|R^N T \psi\|_{L^p(G)} \leq C_N \|R_p^{-\nu_T + N} \psi\|_{L^p(G)}.$$ 

Consequently

$$\|T \psi\|_p + \|R^N T \psi\|_p \leq C_0 \|R_p^{-\nu_T} \psi\|_p + C_N \|R_p^{-\nu_T + N} \psi\|_p.$$ 

By Theorem 4.3 Part (3), the left-hand side is equivalent to the Sobolev norm of $T \psi$ in $L^p_{\nu_N}(G)$ whereas the following shows that the right-hand side is equivalent to the Sobolev norm of $\psi$ in $L^p_{\nu_T + \nu_N}(G)$. Indeed, we have by Theorem 3.5 Part (1), that

$$\|R_p^{-\nu_T} \psi\|_p \leq C \|\psi\|_p^{1-\theta} \|R_p^{-\nu_T + N} \psi\|_p^{\theta} \leq C \max \left(\|\psi\|_p, \|R_p^{-\nu_T + N} \psi\|_p\right),$$

where $\theta = (\nu_T)/((\nu_T + N)$ since $a^{1-\theta} b^\theta \leq \max(a, b)$ for every $a, b \geq 0$ and $\theta \in [0, 1]$.

Therefore $T$ is continuous from $L^p_{\nu_{N+\nu_T}}(G)$ to $L^p_{\nu_N}(G)$. By interpolation (see Theorem 4.8), it is also continuous from $L^p_{s+\nu_T}(G)$ to $L^p_s(G)$ for every $s \geq 0$. Again by duality, see Corollary 4.6 this shows that this is also true for $s \leq 0$.

Since $T$ is continuous from $L^p_s(G)$ to $L^p_{s-\nu_T}(G)$ for $s > \nu_T$, there exists $C = C_{s,T} > 0$ such that for any $\phi \in \mathcal{S}(G),$

$$\|T \phi\|_p + \|R^{s-\nu_T} T \phi\|_p \leq C \left(\|\phi\|_p + \|R^s \phi\|_p\right).$$

In particular applying this to $\phi \circ D_r$ for $r > 0$, we obtain after simplification:

$$r^{\nu_T} \|T \phi\|_p + r^s \|R^{s-\nu_T} T \phi\|_p \leq C \left(\|\phi\|_p + r^s \|R^s \phi\|_p\right).$$

Since this is true for any $r > 0$, by dividing by $r^s$ and letting $r \to \infty$, we obtain

$$\|R^{s-\nu_T} T \phi\|_p \leq C \|R^s \phi\|_p.$$

This concludes the proof of Theorem 4.9.

### 4.4. Independence with respect to Rockland operators, and integer orders.

In this Section, we show that the Sobolev spaces do not depend on a particular choice of a Rockland operator. Consequently Theorems 4.3 and 4.8, Corollary 4.6 and Proposition 4.7 hold independently of any chosen Rockland operator $R$.

We will need the following property:

**Lemma 4.10.** Let $R$ be a Rockland operator on $G$ of homogeneous degree $\nu$ and let $\ell \in \mathbb{N}_0$, $p \in (1, \infty)$. Then the space $L^p_{\nu \ell}(G)$ is the collection of functions $f \in L^p(G)$ such that
$X^\alpha f \in L^p(G)$ for any $\alpha \in \mathbb{N}^{n_0}$ with $[\alpha] = \nu \ell$. Moreover the map $\phi \mapsto \|\phi\|_p + \sum_{[\alpha]=\nu \ell} \|X^\alpha \phi\|_p$ is a norm on $L^p_{\nu \ell}(G)$ which is equivalent to the Sobolev norm.

Proof of Lemma 4.10. Writing $R^\ell = \sum_{[\alpha]=\nu \ell} c_{\alpha,\ell} X^\alpha$ we have on one hand,

$$\exists C > 0 \quad \forall \phi \in S(G) \quad \|R^\ell \phi\|_p \leq \max |c_{\alpha}| \sum_{[\alpha]=\nu \ell} \|X^\alpha \phi\|_p.$$  

Adding $\|\phi\|_{L^p}$ on both sides of this inequality implies by Theorem 4.3, part (2), that

$$\exists C > 0 \quad \forall \phi \in S(G) \quad \|\phi\|_{L^p_{[\alpha]}} \leq C \left( \|\phi\|_{L^p} + \sum_{[\alpha]=\nu \ell} \|X^\alpha \phi\|_p \right).$$

On the other hand, by Theorem 4.9, for any $\alpha \in \mathbb{N}^{n_0}$, the operator $X^\alpha$ maps continuously $L^p_{[\alpha]}(G)$ to $L^p(G)$, hence

$$\exists C > 0 \quad \forall \phi \in S(G) \quad \sum_{[\alpha]=\nu \ell} \|X^\alpha \phi\|_p \leq C \|\phi\|_{L^p_{[\alpha]}}.$$  

Lemma 4.10 follows from these estimates.

One may wonder whether Lemma 4.10 would be true not only for integer exponents of the form $s = \nu \ell$ but for any integer $s$. In fact other Sobolev spaces on a graded Lie group were defined by Goodman in [10, Sec. III. 5.4] following this idea. See Section 5.3.

We can now show the main result of this section, that is, that the Sobolev spaces on graded groups are independent of the chosen positive Rockland operators.

Theorem 4.11. For each $p \in (1, \infty)$, the $L^p$-Sobolev spaces on $G$ associated with any positive Rockland operators coincide. Moreover the Sobolev norms associated to two positive Rockland operators are equivalent.

Proof of Theorem 4.11. Let $R_1$ and $R_2$ be two positive Rockland operators on $G$ of homogeneous degree $\nu_1$ and $\nu_2$, respectively. Then $R_1^{\nu_2}$ and $R_2^{\nu_1}$ are two positive Rockland operators with the same homogeneous degree $\nu = \nu_1 \nu_2$. Their associated Sobolev spaces of exponent $\nu \ell = \nu_1 \nu_2 \ell$ for any $\ell \in \mathbb{N}_0$ coincide and have equivalent norms by Lemma 4.10. By interpolation (see Theorem 4.8), this is true for any Sobolev spaces of exponent $s \geq 0$, and by duality for any exponent $s \in \mathbb{R}$.  

Corollary 4.12. Let $R^{(1)}$ and $R^{(2)}$ be two positive Rockland operators on $G$ with degrees of homogeneity $\nu_1$ and $\nu_2$. Then for any $s \in \mathbb{R}$, the operator $(I + R^{(1)})^{\frac{s}{\nu_1}}(I + R^{(2)})^{-\frac{s}{\nu_2}}$ extends boundedly on $L^p(G)$, $p \in (1, \infty)$.

Proof of Corollary 4.12. We view the operator $(I + R^{(2)})^{-\frac{s}{\nu_2}}$ as a bounded operator from $L^p(G)$ to $L^2(G)$ and use the norm $f \mapsto \|(I + R^{(1)})^{\frac{s}{\nu_1}} f\|_p$ on $L^p(G)$.  

Thanks to Theorem 4.11, we can now improve our duality result given in Corollary 4.5.
Proposition 4.13. Let $L^p_s(G)$, $p \in [1, \infty) \cup \left\{ \infty \right\}$ and $s \in \mathbb{R}$, be the Sobolev spaces on a graded group $G$.

For any $s \in \mathbb{R}$ and $p \in [1, \infty)$, the dual space of $L^p_s(G)$ is isomorphic to $L^{p'}_{-s}(G)$ via the distributional duality, where $p'$ is the conjugate exponent of $p$ if $p \in (1, \infty)$, and $p' = \infty_o$ if $p = 1$.

For any $s \leq 0$ and $p = \infty_o$, the dual space of $L^\infty_{s}(G)$ is isomorphic to $L^1_{-s}(G)$ via the distributional duality.

If $p \in (1, \infty)$ then the Banach space $L^p_s(G)$ is reflexive. It is also the case for $s \leq 0$ and $p = \infty_o$, and for $s \geq 0$ and $p = 1$.

We can also show that multiplication by a bump function is continuous on Sobolev spaces:

Proposition 4.14. For any $\phi \in \mathcal{D}(G)$, $p \in (1, \infty)$ and $s \in \mathbb{R}$, the operator $f \mapsto f\phi$ defined for $f \in \mathcal{S}(G)$ extends continuously into a bounded map from $L^p_s(G)$ to itself.

Proof. The Leibniz' rule for the $X_j$’s and the continuous inclusions in Theorem 4.3(4) imply easily that for any fixed $\alpha \in \mathbb{N}^n_0$ there exist a constant $C = C_{\alpha, \phi} > 0$ and a constant $C' = C'_{\alpha, \phi} > 0$ such that

$$\forall f \in \mathcal{D}(G) \quad \|X^\alpha (f\phi)\|_p \leq C \sum_{|\beta| \leq |\alpha|} \|X^\beta f\|_p \leq C'\|f\|_{L^p_{|\alpha|}(G)}.$$

Lemma 4.10 yields the existence of a constant $C'' = C''_{\alpha, \phi} > 0$ such that

$$\forall f \in \mathcal{D}(G) \quad \|f\phi\|_{L^p_{\ell\nu}(G)} \leq C''\|f\|_{L^p_{\ell\nu}(G)}$$

for any integer $\ell \in \mathbb{N}_0$ and any degree of homogeneity $\nu$ of a Rockland operator.

This shows the statement for the case $s = \nu\ell$. The case $s > 0$ follows by interpolation (see Theorem 4.8), and the case $s < 0$ by duality (see Proposition 4.13). \qed

4.5. Properties of $L^2_s(G)$. The case $L^2(G)$ has some special features, mainly being a Hilbert space, that we will discuss here.

Many of the proofs in this paper could be simplified if we had just considered the case $L^p$ with $p = 2$. For instance, let us consider a positive Rockland operator $R$ and its self-adjoint extension $R_2$ on $L^2(G)$. One can define the fractional powers of $R_2$ and $I + R_2$ by functional analysis. Then one can obtain the properties of the kernels of the Riesz and Bessel potentials with similar methods as in Corollary 3.10.

The proof of the properties of the associated Sobolev spaces $L^2_s(G)$ would be the same in this particular case, maybe slightly helped occasionally by the Hölder inequality being replaced by the Cauchy-Schwartz inequality. A noticeable exception is that Lemma 4.10 can be obtained directly in the case $L^p$, $p = 2$, from the estimates due to Helffer and Nourrigat in [11].
The main difference between \( L^2 \) and \( L^p \) Sobolev spaces is the structure of Hilbert spaces of \( L^2_s(G) \) whereas the other Sobolev spaces \( L^p_s(G) \) are ‘only’ Banach spaces:

**Proposition 4.15** (Hilbert space \( L^2_s \)). Let \( G \) be a graded group.

For any \( s \in \mathbb{R} \), \( L^2_s(G) \) is a Hilbert space with inner product given by

\[
(f,g)_{L^2_s(G)} := \int_G (1 + \mathcal{R}_2)^{\frac{s}{2}} f(x) \overline{(1 + \mathcal{R}_2)^{\frac{s}{2}} g(x)} dx,
\]

where \( \mathcal{R} \) is a positive Rockland operator of homogeneous degree \( \nu \).

If \( s > 0 \), an equivalent inner product is

\[
(f,g)_{L^2_s(G)} := \int_G f(x) \overline{g(x)} dx + \int_G \mathcal{R}_2^{\frac{s}{2}} f(x) \overline{\mathcal{R}_2^{\frac{s}{2}} g(x)} dx.
\]

If \( s = \nu \ell \) with \( \ell \in \mathbb{N}_0 \), an equivalent inner product is

\[
(f,g) = (f,g)_{L^2_s(G)} + \sum_{|\alpha| = \nu \ell} (X_\alpha f, X_\alpha g)_{L^2_s(G)}.
\]

Proposition 4.15 is easily checked, using the structure of Hilbert space of \( L^2(G) \).

5. Further properties of Sobolev spaces

In this section we show a Sobolev embedding theorem, and this will require showing that the operators of type 0 act continuously on Sobolev spaces. We also compare the spaces we have constructed in the previous section with other possible definitions of Sobolev spaces.

5.1. Operators of type 0 acting on Sobolev spaces. In this section we show that the result given in Theorem 2.4 for operator of type 0 can be extended to Sobolev spaces:

**Theorem 5.1.** Any operator of type \( \nu_o \) with \( \text{Re} \nu_o = 0 \), extends to a bounded operator on \( L^p_s(G) \) for any \( p \in (1, \infty) \) and \( s \in \mathbb{R} \).

In the statement and in the proof, we keep the same notation for an operator on \( \mathcal{D}(G) \rightarrow \mathcal{D}'(G) \) and its possible bounded extensions to some Sobolev spaces in order to ease the notation.

Before giving the proof of Theorem 5.1 let us comment on similar results in related contexts. In the case of \( \mathbb{R}^n \) (and similarly for compact Lie groups), the continuity on Sobolev spaces would be easy since \( T_\kappa \) would commute with the Laplace operator but the homogeneous setting requires a more substantial argument. On any stratified group, Theorem 5.1 was shown by Folland in [3, Theorem 4.9]. However the proof in this context uses the existence of a positive Rockland operator with a unique homogeneous fundamental solution, namely ‘the’ (any) sub-Laplacian. If we wanted to follow closely the same line of arguments, we would have to assume that the group is equipped with a Rockland operator of homogeneous degree \( \nu \) with \( \nu < Q \). This is not always the case for a graded group (it suffices to
consider for example the three dimensional Heisenberg group \( \widehat{\mathbb{H}}_1 \) with a graded non-stratified structure defined in Section [5.3]. We present here a proof which is valid under no restriction in the graded case. As in the stratified case, the main problem is to check at every step that formal convolutions between different kernels make sense, see the discussion before Proposition 2.6.

Proof of Theorem 5.1. Let \( \kappa \) be a kernel of type \( \nu_o \) with \( \text{Re} \nu_o = 0 \) and let \( \mathcal{R} \) be a positive Rockland operator of homogeneous degree \( \nu \). By Corollary [3.10] (i), if \( a \in (0, Q) \), \( \mathcal{I}_a \) is a kernel of type \( a \), and for any \( \phi \in \mathcal{S}(G) \), we have

\[
\mathcal{R}_{a}^\frac{\nu}{2} \phi \in L^p(G) \cap L^{q}(G) \quad \text{and} \quad \phi = (\mathcal{R}_{a}^\frac{\nu}{2} \phi) \ast \mathcal{I}_a = (\mathcal{R}_{a}^\frac{\nu}{2} \phi) \ast \mathcal{I}_a,
\]

where, for instance, \( \bar{q} = \frac{1}{2}(1 + \frac{Q}{a}) < \frac{Q}{a} \). By Proposition 2.6 (ii), \( \mathcal{I}_a \ast \kappa \) is a kernel of type \( a + \nu_o \) with \( \text{Re} (a + \nu_o) = a \in (0, Q) \), and

\[
T_\kappa \phi = \phi \ast \kappa = \left((\mathcal{R}_{a}^\frac{\nu}{2} \phi) \ast \mathcal{I}_a\right) \ast \kappa = (\mathcal{R}_{a}^\frac{\nu}{2} \phi) \ast (\mathcal{I}_a \ast \kappa) \quad \text{(in some} L^q(G)\text{)}.
\]

This implies that for any \( j = 1, \ldots, n \), \( \kappa_j := X_j (\mathcal{I}_{\nu_j} \ast \kappa) \) is a kernel of type \( \nu_o \) and that the following operators coincide on \( \mathcal{S}(G) \)

\[
X_j T_\kappa = T_{\kappa_j} \mathcal{R}_{a}^\frac{\nu}{2}.
\]

Since \( T_{\kappa_j} \) is \( L^p \)-bounded (see Theorem [2.4]), we have obtained for any \( j = 1, \ldots, n \) and any \( \phi \in \mathcal{S}(G) \):

\[
\|X_j T_\kappa \phi\|_p = \|T_{\kappa_j} \mathcal{R}_{a}^\frac{\nu}{2} \phi\|_p \leq C \|\mathcal{R}_{a}^\frac{\nu}{2} \phi\|_p \leq C' \|\phi\|_{L^p, j},
\]

using Theorem 4.3 (2) for the last inequality. Note that this yields for any two indices \( j_1, j_2 = 1, \ldots, n \),

\[
\|X_{j_2}X_{j_1} T_\kappa \phi\|_p \leq C_1 \|X_{j_1} \phi\|_{L^p, j_2} \leq C_2 \|\phi\|_{L^p, j_2 + \nu_1},
\]

since \( X_{j_1} \) maps \( L^p_{j_2 + \nu_1} \) to \( L^p_{\nu_1} \) boundedly (see Theorem 4.9). Recursively, writing any \( X^\alpha \) as the composition of various \( X_j \) yields

\[
\exists C = C_\alpha \quad \forall \phi \in \mathcal{S}(G) \quad \|X^\alpha T_\kappa \phi\|_p \leq C \|\phi\|_{L^p, |\alpha|}. \]

This is true for any \( \alpha \in \mathbb{N}^n_0 \), the case \( \alpha = 0 \) following from Theorem 2.4. For each \( \ell \in \mathbb{N}_0 \) fixed, we now sum over \( |\alpha| = 0, \ell \nu \), to get

\[
\|T_\kappa \phi\|_p + \sum_{|\alpha| = \ell \nu} \|X^\alpha T_\kappa \phi\|_p \leq C \left( \|\phi\|_{L^p_0} + \sum_{|\alpha| = \ell \nu} \|\phi\|_{L^p_{|\alpha|}} \right) \leq C' \|\phi\|_{L^p_\nu}.
\]

The left hand side is equivalent to \( \|T_\kappa \phi\|_{L^p_\nu} \) by Lemma 4.10. Thus we obtain

\[
\exists C = C_\ell \quad \forall \phi \in \mathcal{S}(G) \quad \|T_\kappa \phi\|_{L^p_\nu} \leq C \|\phi\|_{L^p_\nu}.
\]

We have obtained that, for any kernel \( \kappa \) of type 0, the corresponding convolution operator \( T_\kappa \) maps continuously \( L^p_\nu \) to itself for any \( s = \ell \nu \) with \( \ell \in \mathbb{N}_0 \) and \( p \in (1, \infty) \). The result for
any $s \in \mathbb{R}$ follows by interpolation (see Theorem 4.8), and duality (see Proposition 4.13). This concludes the proof of Theorem 5.1. □

5.2. Sobolev embedding theorem. In this section, we show the analogue of the classical fractional integration theorems of Hardy-Littlewood and Sobolev. The main difference is that the topological dimension $n$ of $G \sim \mathbb{R}^n$ is replaced by the homogeneous dimension $Q$. The stratified case was proved by Folland in [3] (mainly Theorem 4.17 therein).

**Theorem 5.2.**

(i) If $1 < p < q < \infty$ and $a, b \in \mathbb{R}$ with $b - a = Q(\frac{1}{p} - \frac{1}{q})$ then we have the following continuous inclusion:  

$$L^p_b \subset L^q_a,$$

that is, for every $f \in L^p_b$, we have $f \in L^q_a$ and there exists a constant $C = C_{a,b,p,q,G} > 0$ independent of $f$ such that  

$$\|f\|_{L^q_a} \leq C \|f\|_{L^p_b}.$$  

(ii) If $p \in (1, \infty)$ and $s > Q/p$ then we have the following inclusion:  

$$L^p_s \subset (C(G) \cap L^\infty(G)),$$

in the sense that any function $f \in L^p_s(G)$ admits a bounded continuous representative (still denoted by $f$). Furthermore there exists a constant $C = C_{s,p,G} > 0$ independent of $f$ such that  

$$\|f\|_{L^\infty} \leq C \|f\|_{L^p_s(G)}.$$  

**Proof.** Let us prove Part (i). Note that, under the condition of the statement, $b - a \in (0, Q)$ and that the relation between $p$ and $q$ is the one giving the $L^p \to L^q$-continuity of operator of type $b - a$ by Theorem 2.4.

We fix a positive Rockland operator $\mathcal{R}$ of homogeneous degree $\nu$ and we assume that $b, a > 0$ and $p, q \in (1, \infty)$ satisfy $b - a = Q(\frac{1}{p} - \frac{1}{q})$.

By Corollary 3.10 (i), $\mathcal{I}_{b-a}$ is a kernel of type $b-a$ and for any $p_1 \in (1, \infty)$ and $\phi \in \mathcal{S}(G)$, $\mathcal{R}^{b-a}_{p_1} \phi \in L^p_{b-a}$ and $\phi = (\mathcal{R}^{b-a}_{p_1} \phi) * \mathcal{I}_{b-a}$. By Theorem 2.4, this implies with $p_1 = p$,

$$\|\phi\|_q \leq C \|\mathcal{R}^{b-a}_{p_1} \phi\|_{L^p}.$$  

For the same reason we also have $\mathcal{R}^{a}_{q} \phi = \mathcal{R}^{b}_{p} \mathcal{I}_{b-a}$ and

$$\|\mathcal{R}^{a}_{q} \phi\|_q \leq C \|\mathcal{R}^{b}_{p} \phi\|_{L^p}.$$  

Adding the two estimates above, we obtain

$$\|\phi\|_q + \|\mathcal{R}^{a}_{q} \phi\|_q \leq C \left( \|\mathcal{R}^{b-a}_{p_1} \phi\|_{L^p} + \|\mathcal{R}^{b}_{p_1} \phi\|_{L^p} \right).$$
Since $b, a$, and $b-a$ are positive, by Theorem 4.3, the left-hand side is equivalent to $\|\phi\|_{L^q_a}$ and both terms in the right-hand side are $\leq C \|\phi\|_{L^q_b}$. Therefore we have obtained:

$$\exists C = C_{a,b,p,q,R} \quad \forall \phi \in S(G) \quad \|\phi\|_{L^q_a} \leq C \|\phi\|_{L^q_b}.$$ 

By density of $S(G)$ in the Sobolev spaces, this shows Part (i) for $b > a > 0$. The result for any $a,b$ follows by duality and interpolation (see Proposition 4.13 and Theorem 4.8). The proof of Part (i) is now complete.

Let us prove Part (ii). Let $p \in (1, \infty)$ and $s > Q/p$. By Corollary 3.10 (ii), we know $B_s \in L^1(G) \cap L^{p'}(G)$, where $p'$ is the conjugate exponent of $p$. For any $f \in L^p_s(G)$, we have

$$f = (I + R_p)^{-\frac{s}{\nu}} f \ast B_s.$$ 

Therefore by Hölder’s inequality,

$$\|f\|_{L^\infty} \leq \|f\|_p \|B_s\|_{p'} = \|B_s\|_{p'} \|f\|_{L^p_s}.$$ 

Moreover for almost every $x$, we have

$$f(x) = \int_G f_s(y)B_s(y^{-1}x)dy = \int_G f_s(xz^{-1})B_s(z)dz.$$ 

Thus for almost every $x,x'$, we have

$$|f(x) - f(x')| = \left| \int_G (f_s(xz^{-1}) - f_s(x'z^{-1})) B_s(z)dz \right| \leq \|B_s\|_{p'} \|f_s(x \cdot) - f_s(x' \cdot)\|_p.$$ 

Translation is continuous on $L^p(G)$, thus as $x' \to x$, $\lim \|f_s(x \cdot) - f_s(x' \cdot)\|_{L^p(G)} = 0$ and consequently $|f(x) - f(x')| \to 0$ almost surely. Hence we can modify $f$ so that it becomes a continuous function. This concludes the proof. $\square$

From the Sobolev embedding theorem (Theorem 5.2 (ii)) and the description of Sobolev spaces with integer exponent (Lemma 4.10) follows easily the following property:

**Corollary 5.3.** Let $G$ be a graded group, $p \in (1, \infty)$ and $s \in \mathbb{N}$. We assume that $s$ is proportional to the homogeneous degree $\nu$ of a positive Rockland operator, that is, $\frac{s}{\nu} \in \mathbb{N}$, and that $s > Q/p$.

Then if $f$ is a distribution on $G$ such that $f \in L^p(G)$ and $X^\alpha f \in L^p(G)$ when $\alpha \in \mathbb{N}_0^n$ satisfies $[\alpha] = s$, then $f$ admits a bounded continuous representative (still denoted by $f$). Furthermore there exists a constant $C = C_{s,p,G} > 0$ independent of $f$ such that

$$\|f\|_{L^\infty} \leq C \left( \|f\|_p + \sum_{[\alpha]=s} \|X^\alpha f\|_p \right).$$
5.3. **Comparison with other definitions of Sobolev spaces.** If the group $G$ is stratified, then we can choose as positive Rockland operator $\mathcal{R} = -\mathcal{L}$ with $\mathcal{L}$ a (negative) sub-Laplacian. The corresponding Sobolev spaces have been developed by Folland in [3] for stratified groups, see also [20]. Folland showed that his Sobolev spaces do not depend on a particular choice of a sub-Laplacian [3, Corollary 4.14], and we have shown the same for our Sobolev spaces and Rockland operators in Theorem 4.11. Therefore, our Sobolev spaces coincide with Folland’s in the stratified case, and gives new descriptions of Folland’s Sobolev spaces.

For instance, let us consider the ‘simplest’ case after the abelian case, that is, the three dimensional Heisenberg group $H_1$, with Lie algebra $h_1 = \mathbb{R}X \oplus \mathbb{R}Y \oplus \mathbb{R}T$ and canonical commutation relations $[X,Y] = T$. This is naturally a stratified group, with canonical (negative) sub-Laplacian $\mathcal{L}_{H_1} := X^2 + Y^2$. We have obtained that the Sobolev spaces (in our sense or equivalently Folland’s) may be defined using any of the positive Rockland operators $-\mathcal{L}_{H_1}$, $\mathcal{L}_{H_1}^2$, or $\mathcal{L}_{H_1}^2 - T^2$.

To compare our Sobolev spaces $L^p_s(G)$ with their Euclidean counterparts $L^p_s(\mathbb{R}^n)$, that is, for the abelian group $(\mathbb{R}^n, +)$, we can proceed as in [3], especially Theorem 4.16 therein. First there can be only local relations between our Sobolev Spaces and the Euclidean Sobolev spaces, since the coefficients of $X_j$’s with respect to the abelian derivatives $\partial_{x_k}$ are polynomials in the coordinate functions $x_\ell$’s, and conversely, the coefficients of $\partial_{x_j}$’s with respect to the abelian derivatives $X_k$ are polynomials in the coordinate functions $x_\ell$’s. Hence we are led to define the following local Sobolev spaces for $s \in \mathbb{R}$ and $p \in (1, \infty)$:

$$L^p_{s,\text{loc}}(G) := \{ f \in \mathcal{D}'(G) : \phi f \in L^p_s(G) \text{ for all } \phi \in \mathcal{D}(G) \}.$$  

By Proposition 4.14, $L^p_{s,\text{loc}}(G)$ contains $L^p_s(G)$. We can compare locally the Sobolev spaces on graded groups and on their abelian counterpart:

**Theorem 5.4.** For any $p \in (1, \infty)$ and $s \in \mathbb{R}$,

$$L^p_{s/v_1,\text{loc}}(\mathbb{R}^n) \subset L^p_{s,\text{loc}}(G) \subset L^p_{s/v_n,\text{loc}}(\mathbb{R}^n).$$

Above, $L^p_{s,\text{loc}}(\mathbb{R}^n)$ denotes the usual local Sobolev spaces, or equivalently the spaces defined by (5.1) in the case of the abelian (graded) group $(\mathbb{R}^n, +)$. Recall that $v_1$ and $v_n$ are respectively the smallest and the largest weights of the dilations. In particular, in the stratified case, $v_1 = 1$ and $v_n$ coincides with the number of steps in the stratification, and with the step of the nilpotent Lie group $G$. Hence in the stratified case we recover Theorem 4.16 in [3].

**Proof of Theorem 5.4.** It suffices to show that the mapping $f \mapsto f\phi$ defined on $\mathcal{D}(G)$ extends boundedly from $L^p_{s/v_1}(\mathbb{R}^n)$ to $L^p_s(G)$ and from $L^p_s(G)$ to $L^p_{s/v_n,\text{loc}}(\mathbb{R}^n)$. By duality and interpolation (see Theorem 4.8 and Proposition 4.13), it suffices to show this for a sequence of increasing positive integers $s$. 
For the $L_{s/v_1}^p(\mathbb{R}^n) \to L_s^p(G)$ case, we assume that $s$ is divisible by the homogeneous degree of a positive Rockland operator. Then we use Lemma 4.10, the fact that the $X^\alpha$ may be written as a combination of the $\partial_x^\beta$ with polynomial coefficients in the $x_{\ell}$’s and that $\max_{|\beta| \leq s}|\beta| = s/v_1$.

For the case of $L_s^p(G) \to L_{s/v_n, loc}^p(\mathbb{R}^n)$, we use the fact that the abelian derivative $\partial_x^\alpha$, $|\alpha| \leq s$, may be written as a combination over the $X^\beta$, $|\beta| \leq s$, with polynomial coefficients in the $x_{\ell}$’s, that $X^\beta$ maps $L^p \to L_{|\beta|}^p$ boundedly together with $\max_{|\beta| \leq s}|\beta| = sv_n$.

□

Proceeding as in [3, p.192], one can convince oneself that Theorem 5.4 can not be improved.

In another direction, Sobolev spaces, and more generally Besov spaces, have been defined on any group of polynomial growth in [5] using left-invariant sub-Laplacians and an associated Littlewood-Payley decomposition. Considering stratified groups and homogeneous left-invariant sub-Laplacians (as in (2.6)), this gives another description of the Sobolev spaces in the stratified case which is equivalent to Folland’s and to ours. However, for a general graded non-stratified group, our Sobolev spaces may differ from the ones in [5] on any Lie group of polynomial growth. For instance, if we consider the three dimensional Heisenberg group endowed with the dilations

$$r \cdot (x, y, t) = (r^3x, r^5y, r^8t).$$

We denote this group $\tilde{H}_1$, it is graded but not stratified. The sub-Laplacian $L_{\tilde{H}_1}$ is not homogeneous and is of degree 10. One can check that that $L_{\tilde{H}_1}$ maps $L_{10}^2(\tilde{H}_1) \to L^2(\tilde{H}_1)$ and $L_{10}^2(\tilde{H}_1) \to L^2(\tilde{H}_1)$ boundedly and this can not be improved. Hence our Sobolev spaces on $\tilde{H}_1$ differ from the Sobolev spaces based on the sub-Laplacian in [3] or equivalently in [5].

Sobolev spaces of integer exponents on graded Lie groups have already been defined by Goodman in [10, Sec. III. 5.4]: the $L^p$ Goodman-Sobolev spaces of order $s \in \mathbb{N}_0$ is the space of function $\phi \in L^p$ such that $X^\alpha \phi \in L^p$ for any $|\alpha| \leq s$. Goodman’s definition does not use Rockland operators but makes sense only for integer exponents. Adapting the proof of Lemma 4.10, one could show easily that the $L^p$ Goodman-Sobolev space of order $s \in \mathbb{N}_0$ always contains our Sobolev space $L_s^p(G)$, and in fact coincides with it if $s$ is proportional to the homogeneous degree $\nu$ of a positive Rockland operator or for any $s$ if the group is stratified.

However, this equality between Goodman-Sobolev spaces and our Sobolev spaces is not true on any general graded group. For instance this does not hold on graded Lie groups whose weights are all strictly greater than 1. Indeed, the $L^p$ Goodman-Sobolev space of order $s = 1$ is $L^p(G)$ which contains $L_s^p(G)$ strictly (see Theorem 4.3 (1)). An example of such a graded group is the three dimensional Heisenberg group $\mathbb{H}_1$ with weights given by (5.2).
One consequence of these strict inclusions together with our results is that the Goodman-Sobolev spaces do not satisfy interpolation properties in general. This together with the fact that, to the authors knowledge, no Sobolev embeddings have been proved for those spaces, limits the use of the Goodman-Sobolev spaces.

Another advantage of the analysis developed in this paper is that it is easy to define homogeneous Sobolev spaces $\dot{L}^p_s(G), s \in \mathbb{R}$ and $p \in (1, \infty)$, as the completion of $f \mapsto \|\mathcal{R}_p f\|_p$ for a Rockland operator $\mathcal{R}$ of degree $\nu$. Moreover simple adaptations of the proofs presented here imply that these spaces satisfy similar properties of inclusions, interpolation and duality as their Euclidean counterparts. As in the non-homogeneous case, one also obtains that these spaces do not depend on a special choice of Rockland operators $\mathcal{R}$.
