Infection Control and Preventive Guidelines against COVID-19 in Dentistry

Priyanka Ramteke¹, Rohan Sawant², Nilker Vimala³, Rahul Ramteke⁴

ABSTRACT

Globally, a new public health disease has emerged threatening the world. Due to the spread of 2019 novel coronavirus which is named as 2019-nCoV and causes severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). Virus is found to be zoonotic, originating in bats and further transmitted to humans through yet unknown intermediary transmitters or channels in Wuhan, Hubei province of China and discovered in December 2019. This novel coronavirus (COVID-19) is highly infectious and now human-to-human transmission is rampant. The coronavirus was recently found in saliva of infected patients after taking their swabs. In this point-of-view article, we discuss the potential of transmission of this virus via the droplets of saliva emitted when the infected person opens his or her mouth. This study has been especially focused on such scenarios arising in the dental practice setup. There seems to be high risk of transmission of novel coronavirus via contact with droplets and aerosols generated during dental clinical procedures. Here, we will be exploring such transmission scenarios and recommend the infection control measures during dental practice to block the person-to-person transmission routes in dental clinics and hospitals.

Keywords: Coronavirus, Dental practice management, Dental public health, Dental transmission, Infection control.

Introduction

The 2019 novel coronavirus (2019-nCoV) or the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) as it is now called, is rapidly spreading from its origin in Wuhan City of Hubei Province of China to the rest of the world.¹ Till 14th of April, more than 2,000,000 cases and 125,000 deaths have been reported due to COVID-19.² In India, the virus has spread to every state and district and causing at least 1,000 daily deaths in early days of September 2020. Coronavirus is a family of enveloped, positive-sense, single-stranded RNA that contain largest known RNA genomes with a length of up to 32 kb.³ They are a family of viruses are known to be zoonotic or transmitted from animals to humans and now human-to-human transmission. Coronavirus have caused two large-scale pandemics in the past two decades, severe acute respiratory syndrome (SARS 2002) and Middle East respiratory syndrome (MERS).⁴ It is found that the novel coronavirus has similarity to coronavirus species found in bats and potentially in pangolins, thus confirming the zoonotic nature of this new virus.⁵ ⁶

This disease outbreak—which started from a local seafood market in China—has grown substantially causing to infect 2,761 people in China, is associated with 80 deaths and 10 additional countries by January 2020.⁷ This has raised an alarm to WHO and as per the WHO situation report (April 20, 2020) update on COVID-19 disease report, there have been more than two million reported cases and more than hundred and fifty thousand deaths worldwide (Fig. 1).³ Due to highly infectious nature of this disease, daily new cases in India have crossed 80,000 by September 2020.

Therefore, measures for prevention, identification, and management must be in place and followed during dental procedures and patient interactions for reducing the further spread of the virus as well as providing requisite dental care to patients. Given the widespread reports of novel coronavirus’s spread to healthcare providers,⁴ ⁹ it is reported that dental care professionals are at severe high risk for nosocomial infection. If appropriate precautions are not taken during their practice, then they can become potential carriers of the disease. Such risks in dental practice can be attributed to the patient interactions unique to dental practice only, which include aerosol generation, handling of sharps for examination, and proximity of the care provider to the patient’s oropharyngeal region. Thus, there is high risk of coming in contact with droplets of saliva and aerosol generated, which has very high potential to spread the disease at a long range.

This article provides a bird’s eye view regarding this new virus and measures to be taken to prevent its spread during dental practice. Since data regarding this virus are rapidly evolving, readers are urged to update themselves frequently by referring WHO website.

Route of Transmission

The common transmission routes of novel coronavirus include transmission by coming in direct contact of the career (cough, sneeze, and droplet inhalation transmission) and surface contact
transmission (contact with oral, nasal, and eye mucous membranes) of had or body parts or any surface containing the virus. Although common clinical manifestations of novel coronavirus infection do not include eye symptoms, it is also found to be causing red eye symptoms in patients and the effect is not only limited to respiratory tracts of the infected person, while it is true that eye exposure may provide an effective way for the virus to enter the body. In addition, studies have shown that 2019-nCoV transmission through saliva or respiratory droplets is most common and there is a high probability for dental practitioner to face such circumstances. The virus was also found to be present in the stool and contamination of the virus in water supply and subsequently transmission via aerosolization during dental procedure/fecal–oral route is also hypothesized. As per current information, transplacental transmission from pregnant women to their fetus or on to newborn baby has not been confirmed. Since 2019-nCoV can be passed directly from person to person by respiratory droplets during contact with infected person, there is emerging evidence that the novel coronavirus can also get transmitted through fomites.

Transmission Routes of 2019-nCoV in Dental Clinics

The pathogenic microorganisms can be transmitted in dental clinics through inhalation of airborne microorganisms generated during treatment of dental patients. These microorganisms can remain suspended in the air for a long time period. Transmission can also occur through direct contact with blood, oral fluids, contact of conjunctival, nasal, or oral mucosa with droplets and aerosols containing microorganisms generated from an infected individual and propelled a short distance by coughing and talking without a mask. The indirect contact which is a surface-to-surface contact with contaminated instruments and/or environmental surfaces, and then subsequently entry through eye, nasal, or mouth infection route. Therefore, there is a high potential for transmission of coronavirus via aerosol, fomites, or the fecal–oral route that may contribute to nosocomial spread in the dental office setting. Infections could be transmitted through any of these conditions involved in an infected individual in dental clinics and hospitals, especially during the outbreak of 2019-nCoV.

Clinical Features

A suspect case is defined as one with fever, sore throat, and cough who has history of travel to China or other areas of persistent local transmission or contact with patients with similar travel history or those with confirmed COVID-19 infection. However, cases with positive results of test may be asymptomatic or even without fever or cough. A confirmed case is a suspect case with a positive molecular test. The clinical features of COVID-19 are varied, ranging from asymptomatic state to acute respiratory distress syndrome and multiorgan dysfunction. The common clinical features include fever (not in all), cough, sore throat, headache, fatigue, headache, myalgia, and breathlessness. Conjunctivitis has also been described. The chest X-ray (CXR) usually shows bilateral infiltrates but may be normal in early disease. The CT is more sensitive and specific. CT imaging generally shows infiltrates, ground-glass opacities, and subsegmental consolidation. It is also abnormal in asymptomatic patients/patients with no clinical evidence of lower respiratory tract involvement. In fact, abnormal CT scans have been used to diagnose COVID-19 in suspect cases with negative molecular diagnosis; many of these patients had positive molecular tests on repeat testing.
Incubation Period
The incubation period of COVID-19 has been estimated at 5–6 days on average, but there is evidence that it could be as long as 14 days, which is now the commonly adopted duration for medical observation and quarantine of (potentially) exposed persons.25

Risk Factors to Dentist
Studies have shown the presence of SARS-CoV-2 in saliva of the affected patients.12,26 To et al. reported that live viruses were present in the saliva of infected individuals by viral culture method.12 It is known that SARS-CoV-2 can bind to human angiotensin-converting enzyme 2 receptors, which are highly concentrated in salivary glands; this may be a possible explanation for the presence of SARS-CoV-2 in secretory saliva.27,28 Dental patients who cough, sneeze, or receive dental treatment including the use of a high-speed handpiece or ultrasonic instruments make their secretions, saliva, or blood aerosolize to the surroundings. Dental apparatus could be contaminated with various pathogenic microorganisms after use or become exposed to a contaminated clinic environment. Therefore, infections can occur through the puncture of sharp instruments or direct contact between mucous membranes and contaminated hands. The airborne spread of severe acute respiratory syndrome coronavirus (SARS-CoV) is well-reported in many literatures. The dental papers show that many dental procedures produce aerosols and droplets that are contaminated with virus.29 Thus, droplet and aerosol transmission of 2019-nCoV are the most important concerns in dental clinics and hospitals, because it is hard to avoid the generation of large amounts of aerosol.19 In addition to the infected patient’s cough and breathing, dental devices, such as high-speed dental handpiece, use high-speed gas to drive the turbine to rotate at high speed and work with running water. Particles of droplets and aerosols are small enough to stay airborne for an extended period before they settle on environmental surfaces or enter the respiratory tract. Thus, the 2019-nCoV has the potential to spread through droplets and aerosols from infected individuals in dental clinics and hospitals.

Steps to Establish COVID-19-Free Dental Practice
Due to the unique characteristics of dental procedures where a large number of droplets and aerosols could be generated, the standard protective measures in daily clinical work are not effective enough to prevent the spread of COVID-19, especially when patients are in the incubation period, are unaware they are infected, or choose to conceal their infection.30

The healthcare workers are at the greatest risk of COVID-19 transmission. In the SARS outbreak of 2002, 21% of those affected were healthcare workers.31 Till date of this article was written, almost 1,500 healthcare workers in China have been infected with 6 deaths. The doctor who first warned about the virus has died too. On March 15, 2020, the New York Times published an article entitled “The Workers Who Face the Greatest Coronavirus Risk”, where an impressive schematic figure (Fig. 2) described that dentists are the “Workers Who Face the Greatest Coronavirus Risk”, where an impressive schematic figure (Fig. 2) described that dentists are the "Workers Who Face the Greatest Coronavirus Risk". Therefore, due to the unique characteristics of dental procedures where a large number of droplets and aerosols could be generated, the standard protective measures in daily clinical work are not effective enough to prevent the spread of COVID-19, especially when patients are in the incubation period, are unaware they are infected, or choose to conceal their infection.30

It is crucial that dental surgeon should be familiar with how 2019-nCoV is spread, how to identify patients with 2019-nCoV infection, and what extra-protective measures should be adopted during the practice, in order to prevent the transmission of 2019-nCoV.32 On 1st April, the ADA also published an Interim Guidance for Management of Emergency and Urgent Dental Care. Below in Table 1, we list the recommended measures for the infection control that should be followed by dental professionals, particularly considering the fact that aerosols and droplets were considered as the main spread routes of 2019-nCoV.33,34

Precautionary Measures to be Adopted before Dental Care Starts

Dentist and Dental Team Preparation
Safety of the staff:

- Ensure that the dental healthcare personnel (DHCP) have received their seasonal flu vaccine.
- Dental healthcare personnel experiencing influenza-like-illness (ILI) (fever with either cough or sore throat, muscle aches, temperature) should not report to work.
- Dental healthcare personnel who are of older age, have a preexisting, medically compromised condition, pregnant, etc., are perceived to be at a higher risk of contracting COVID-19 from contact with known or suspected COVID-19 patients.
- All DHCPs should self-monitor their condition by remaining alert to any respiratory symptoms (e.g., cough, shortness of breath, sore throat) and check their temperature twice a day, regardless of the presence of other symptoms consistent with a COVID-19 infection. Dental offices should create a plan for whom to contact if an employee develops fever or respiratory symptoms to determine whether medical evaluation is necessary.
- To prevent transmission to DHCP or other patients, contact your local health department immediately if you suspect a patient has COVID-19. You can also contact your state health department. It is important to report such condition in Mobile Apps of the government. For instance in India, Arogya Setu Mobile App should be used to update details.
- “Designate convalescent (DHCP) provision of care to known or suspected COVID-19 patients (those who have clinically recovered from COVID-19 and may have some protective immunity) to preferentially provide care”. This means that providers who have recently contracted and recovered from a COVID-19 infection should be the preferred personnel providing care.
- “Maintain an inventory of available personal protective equipment (PPE) supplies (e.g., surgical masks, surgical gowns, surgical gloves, face shields) and ensure it’s use at appropriate time”.

Fig. 2: March 15, 2020, the New York Times entitled impressive schematic report: “The Workers Who Face the Greatest Coronavirus Risk”
Office setup:
- Remove magazines, reading materials, toys, and other objects that may be touched by others and which are not easily disinfected.
- Print and place signage in the dental office for instructing patients on standard recommendations for respiratory hygiene/cough etiquette and social distancing.

Appointment scheduling:
- Schedule appointments apart enough to minimize possible contact with other patients in the waiting room.
- Prevent patients from bringing companions to their appointment, except for instances where the patient requires assistance (e.g., pediatric patients, people with special needs, elderly patients, etc.).
- If companions are allowed for patients receiving treatment, they should also be screened for signs and symptoms of COVID-19 during patient check-in and should not be allowed entry into the facility if signs and symptoms are present (e.g., fever, cough, shortness of breath, sore throat). Companions should not be allowed in the dental office if perceived to be at a high risk of contracting COVID-19 (e.g., having a preexisting medically compromised condition). Any person accompanying a patient should be prohibited in the dental operatory.

Screening for COVID-19 Status and Triaging for Dental Treatment
Phone screening for COVID-19:
- A recommendation from WHO as of 16th March was for "Dentists nationwide to postpone elective procedures for the next three weeks. Concentrating on emergency dental care will allow us to care for our emergency patients and alleviate the burden that dental emergencies would place on hospital emergency departments". State and local mandates as well as regional variation in infection rates may affect the guidance on postponement period going forward (Algorithm 1) (Fig. 3A).
- Make every effort to interview the patient by telephone, text monitoring system, or video conference before the visit.

Who can be Seen in the Dental Setting?
- If an emergency or urgent dental patient does not have a fever and is otherwise without even mild symptoms consistent with COVID-19 infection (e.g., fever, sore throat, cough, difficulty breathing), they can be seen in dental settings with appropriate protocols and personal protective equipment (PPE) in place (Algorithms 2 and 3) (Figs 3B and 3C).
- If an emergency or urgent dental patient has a fever strongly associated with a dental diagnosis (e.g., pulpal and periapical dental pain and intraoral swelling is present), but no other signs/symptoms of COVID-19 infection (e.g., fever, sore throat, cough, difficulty breathing), they can be seen in dental settings with appropriate protocols and PPE in place (Algorithms 2 and 3).
- If an emergency or urgent dental patient has a fever strongly associated with a dental diagnosis (e.g., pulpal and periapical dental pain and intraoral swelling is present), but no other signs/symptoms of COVID-19 infection (e.g., fever, sore throat, cough, difficulty breathing), they can be seen in dental settings with appropriate protocols and PPE in place (Algorithms 2 and 3).
- If an emergency or urgent dental patient does exhibit signs and symptoms of respiratory illness, the patient should be referred for emergency care where appropriate transmission-based precautions are available (Algorithm 2).
- Patients with a resolved COVID-19 infection can be seen in a dental setting:
  - At least 3 days (72 hours) since COVID-19 infection symptoms resolved AND
  - At least 7 days since their symptoms first appeared (defined as resolution of fever without the use of fever-reducing medications and improvement in respiratory symptoms) (e.g., cough, shortness of breath).

Table 1: Interim guidance for management of emergency and urgent dental care

| Before dental care starts | After dental care is provided |
|---------------------------|------------------------------|
| (1) Dentist and dental team preparation. | (7) In-between patients |
| (2) Screening for COVID-19 status and triaging for dental treatment. | (8) Postoperative instructions for patients. |

Algorithm 1: Interim Guidance for Triage for Patients for Emergency and Urgent Dental Care

Have you experienced trauma?

Yes

Trauma involving facial bones, potentially obstructing airways

Dental trauma only

Emergent

Refer patient to emergency department

No

Do you have a fever AND swelling on your face or inside your mouth?

Yes

1–5 (mild to moderate)

No

What is your pain level on a scale of 1–10?

6–10 (severe or intolerable) follow-up question to ask: Are you having trouble swallowing? Are you having trouble opening your mouth?

Do you need any of the following?

Yes

- Suture removal
- Denture repair or adjustment prior to medical treatment or due to trouble eating
- Dental treatment required prior to medical treatment (e.g., radiotherapy)
- Biopsy of abnormal tissue
- Final crown/bridge cementation if the temporary restoration is lost or broken

No

Can pain or discomfort be tolerated or managed at home for 2–3 weeks

Yes

Delay scheduling appointment until further notice (e.g., in accordance with state and local guidance) and instruct the patients to contact office if condition worsens

No

Use the Algorithm 2: Screening to identify COVID-19 infection for emergency and urgent dental patients algorithm to screen urgent patients for COVID-19 infection to determine if patients can be seen in dental setting.

Urgent

Routine or non-urgent

Delay scheduling appointment until further notice (e.g., in accordance with state and local guidance) and instruct the patients to contact office if condition worsens, if applicable.

Emergent

Use the Algorithm 2: Screening to identify COVID-19 infection for emergency and urgent dental patients algorithm to screen emergency patients for COVID-19 infection to determine if patients can be seen in dental setting.

Pain could be related to these urgent conditions:

- Severe dental pain from pulpal inflammation
- Pericoronitis or third-molar pain
- Surgical postoperative ostiitis, dry socket dressing changes
- Abscess, or localized bacterial infection resulting in localized pain and swelling
- Tooth fracture resulting in pain or causing soft tissue trauma
- Dental trauma with avulsion/luxation
- Final crown/bridge cementation if the temporary restoration is lost, broken or causing gingival irritation
- Replacing temporary filling on endo access openings in patients experiencing pain
- Snapping or adjustment of an orthodontic wire or appliances piercing or ulcerating the oral mucosa

Use the Algorithm 2: Screening to Identify COVID-19 Infection for Emergency and Urgent Dental Patients algorithm to screen urgent patients for COVID-19 infection to determine if the patients can be seen in dental setting.

Fig. 3A: Interim guidance for triaging patients for emergency and urgent dental care
Referrals: If the patient needs to be referred for COVID-19 testing, they should be provided detailed instructions on when/where to go for testing, how to justify the need for testing to the testing facility visited, and how to contact the dental clinic to report test results. Clinic director and/or coordinators should maintain a list of patients who will not be coming in for in-person visits in charts or find another mechanism that fits into the clinic’s workflow. It is critical that a list of dental patients that have been referred to other settings due to suspected COVID-19 infection be maintained (Figs 4A and 4B).

Instructions for Patient Arrival

Social distancing and waiting area: Facilities should have space in waiting areas for ill patients to sit separated from other patients by at least 6 feet. Medically stable patients might opt to wait in a personal vehicle or outside the healthcare facility where they can be contacted by mobile phone when it is their turn to be seen.

Infection control etiquette: Put on a cloth face covering or face mask before entering the building and await screening for fever and symptoms of COVID-19. Face mask should be worn properly covering nose and mouth. Hand sanitizer dispensing machine should be installed with appropriate instructions on its usage. Perform frequent hand hygiene, and restrict their visit to the patient’s room or other area designated by the facility.

During Dental Care

Standard and Transmission Precautions and PPE

Standard precautions: Dental healthcare personnel should adhere to standard precautions, which “are the minimum infection prevention practices include: Hand hygiene, use of PPE, respiratory hygiene/etiquette, sharps safety, safe injection practices, sterile instruments and devices, clean and disinfected environmental surfaces”.

Transmission-based precautions: If available, DHCP should implement transmission-based precautions. “Necessary transmission-based precautions might include patient placement (e.g., isolation) maintaining physical distance, adequate room ventilation, respiratory protection (e.g., N-95 masks) for DHCP, or postponement of nonemergency dental procedures”.

Use of masks and respirators: Wear a surgical mask and eye protection with solid side shields or a face shield to protect mucous membranes of the eyes, nose, and mouth during procedures likely to generate splashing or spattering (large droplets) of blood or other body fluids.

Surgical masks are one time use only, and one mask should be used per patient.

If your mask is damaged or soiled, or if breathing through the mask becomes difficult, you should remove the face mask, discard it safely, and replace it with a new one.
Algorithm 3: Interim Guidance to Minimize Risk of COVID-19 Transmission for Emergency and Urgent Dental Patients and HCP

Summary of Procedures
1. Clinic staff should speak to all patients 1–2 working days (or sooner if able) before any scheduled session.
2. Call patients for whom in-person visit may not be necessary and re-schedule.
3. See emergency triage and COVID-19 infection screening procedures.

Emergency and urgent dental patients in this algorithm are asymptomatic, have no known COVID-19 exposure, recovered from COVID-19 infection, or have recently undergone testing and do not have COVID-19 infection.

Is this patient scheduled for an emergency in-person appointment?

Yes

Does diagnosis necessitate an aerosol-generating procedure?

Yes

A
You and your staff have N95 respirators fitted to your face, full-face shields, and basic clinical PPE (including eye protection), and you are prepared to follow approved disinfection procedures immediately after this and every procedure.

Risk for transmission to HCP and patients
Low risk
No 14-day quarantine required

Moderate risk*
Use clinical judgment and take all precautions to prevent transmission. Suggest that the patient is tested for COVID-19 infection after dental treatment. If positive, dental HCP should quarantine for 14 days.

Moderate-high risk
Given that asymptomatic patients may carry the virus, CDC suggests a 14-day quarantine. Use clinical judgment and take all precautions to prevent transmission. If treatment is implemented, require that the patient is tested for COVID-19 infection immediately after dental care; if positive, dental HCP should quarantine for 14 days.

Quarantine for HCPs

Recommended treatment plan for patient
Treat patient

* A less protective option than N95 respirators is the use of a surgical face mask with a full-face shield; use of a surgical face mask alone may be considered if the supply chain of respirators cannot meet demand with the understanding that this may increase the risk of infection of dental healthcare professionals engaged in the care and community transmission.

These algorithms are interim guidance informed by the latest recommendations from healthcare agencies (e.g., World Health Organization, Centers for Disease Control and Prevention) and the scientific literature. They will be revised and updated as new data emerge.

HCP: healthcare personnel; PPE: personal protective equipment

See next page for key remarks regarding Algorithm 3

Fig. 3C: Interim guidance to minimize risk of COVID-19 transmission for emergency and urgent dental patients and HCP
Fig. 4A: Case report form for COVID-19-infected person
Donning and doffing (Figs 5A to 5C)

Technical Approaches and Equipment to Help Reduce Transmission (Handpieces, Equipment, etc.)

- Since SARS-CoV-2 may be vulnerable to oxidation, use 1.5% hydrogen peroxide (commercially available in India) or 0.2% povidone as a pre-procedural mouth rinse. There are no clinical studies supporting the virucidal effects of any pre-procedural mouth rinse against SARS-CoV-2.

- Dental healthcare personnel may use “extraoral dental radiographs, such as panoramic radiographs or cone beam CT, are appropriate alternatives” to intraoral dental radiographs.
SEQIENCE FOR PUTTING ON PERSONAL PROTECTIVE EQUIPMENT (PPE)

The type of PPE used will vary based on the level of precautions required, such as standard and contact, droplet or airborne infection isolation precautions. The procedure for putting on and removing PPE should be tailored to the specific type of PPE.

1. GOWN
   - Fully cover torso from neck to knees, arms to end of wrists, and wrap around the back
   - Fasten in back of neck and waist

2. MASK OR RESPIRATOR
   - Secure ties or elastic bands at middle of head and neck
   - Fit flexible band to nose bridge
   - Fit snug to face and below chin
   - Fit-check respirator

3. GOGGLES OR FACE SHIELD
   - Place over face and eyes and adjust to fit

4. GLOVES
   - Extend to cover wrist of isolation gown

USE SAFE WORK PRACTICES TO PROTECT YOURSELF AND LIMIT THE SPREAD OF CONTAMINATION

- Keep hands away from face
- Limit surfaces touched
- Change gloves when torn or heavily contaminated
- Perform hand hygiene

Fig. 5A: Donning during dental care
HOW TO SAFELY **REMOVE** PERSONAL PROTECTIVE EQUIPMENT (PPE)

**EXAMPLE 1**

There are a variety of ways to safely remove PPE without contaminating your clothing, skin, or mucous membranes with potentially infectious materials. Here is one example. **Remove all PPE before exiting the patient room** except a respirator, if worn. Remove the respirator **after** leaving the patient room and closing the door. Remove PPE in the following sequence:

**1. GLOVES**
- Outside of gloves are contaminated!
- If your hands get contaminated during glove removal, immediately wash your hands or use an alcohol-based hand sanitizer
- Using a gloved hand, grasp the palm area of the other gloved hand and peel off first glove
- Hold removed glove in gloved hand
- Slide fingers of ungloved hand under remaining glove at wrist and peel off second glove over first glove
- Discard gloves in an infectious* waste container

**2. GOGGLES OR FACE SHIELD**
- Outside of goggles or face shield are contaminated!
- If your hands get contaminated during goggles or face shield removal, immediately wash your hands or use an alcohol-based hand sanitizer
- Remove goggles or face shield from the back by lifting head band or ear pieces
- If the item is reusable, place in designated receptacle for reprocessing. Otherwise, discard in an infectious* waste container

**3. GOWN**
- Gown front and sleeves are contaminated!
- If your hands get contaminated during gown removal, immediately wash your hands or use an alcohol-based hand sanitizer
- Unfasten gown ties, taking care that sleeves don’t contact your body when reaching for ties
- Pull gown away from neck and shoulders, touching inside of gown only
- Turn gown inside out
- Fold or roll into a bundle and discard in an infectious* waste container

**4. MASK OR RESPIRATOR**
- Front of mask/respirator is contaminated — **DO NOT TOUCH**!
- If your hands get contaminated during mask/respirator removal, immediately wash your hands or use an alcohol-based hand sanitizer
- Grasp bottom ties or elastics of the mask/respirator, then the ones at the top, and remove without touching the front
- Discard in an infectious* waste container

**5. WASH HANDS OR USE AN ALCOHOL-BASED HAND SANITIZER IMMEDIATELY AFTER REMOVING ALL PPE**

*An infectious waste container is used to dispose of PPE that is potentially contaminated with Ebola virus.

**PERFORM HAND HYGIENE BETWEEN STEPS IF HANDS BECOME CONTAMINATED AND IMMEDIATELY AFTER REMOVING ALL PPE**

Fig. 5B: Doffing during dental care (example 1)
HOW TO SAFELY REMOVE PERSONAL PROTECTIVE EQUIPMENT (PPE)
EXAMPLE 2

Here is another way to safely remove PPE without contaminating your clothing, skin, or mucous membranes with potentially infectious materials. Remove all PPE before exiting the patient room except a respirator, if worn. Remove the respirator after leaving the patient room and closing the door. Remove PPE in the following sequence:

1. GOWN AND GLOVES
   • Gown front and sleeves and the outside of gloves are contaminated!
   • If your hands get contaminated during gown or glove removal, immediately wash your hands or use an alcohol-based hand sanitizer
   • Grasp the gown in the front and pull away from your body so that the ties break, touching outside of gown only with gloved hands
   • While removing the gown, fold or roll the gown inside-out into a bundle
   • As you are removing the gown, peel off your gloves at the same time, only touching the inside of the gloves and gown with your bare hands. Place the gown and gloves into a waste container

2. GOGGLES OR FACE SHIELD
   • Outside of goggles or face shield are contaminated!
   • If your hands get contaminated during goggles or face shield removal, immediately wash your hands or use an alcohol-based hand sanitizer
   • Remove goggles or face shield from the back by lifting head band and without touching the front of the goggles or face shield
   • If the item is reusable, place in designated receptacle for reprocessing. Otherwise, discard in a waste container

3. MASK OR RESPIRATOR
   • Front of mask/respirator is contaminated — DO NOT TOUCH!
   • If your hands get contaminated during mask/respirator removal, immediately wash your hands or use an alcohol-based hand sanitizer
   • Grasp bottom ties or elastics of the mask/respirator, then the ones at the top, and remove without touching the front
   • Discard in a waste container

4. WASH HANDS OR USE AN ALCOHOL-BASED HAND SANITIZER IMMEDIATELY AFTER REMOVING ALL PPE

PERFORM HAND HYGIENE BETWEEN STEPS IF HANDS BECOME CONTAMINATED AND IMMEDIATELY AFTER REMOVING ALL PPE

Fig. 5C: Doffing during dental care (example 2)
during the outbreak of COVID-19, as the latter can stimulate saliva secretion and coughing.

- Reduce aerosol production as much as possible, as the transmission of COVID-19 seems to occur via droplets or aerosols, and DHCP should prioritize the use of hand instrumentation. Carisolv and hand scaler are recommended for caries removal and periodontal scaling, in order to minimize the generation of aerosol as much as possible.

- Dental healthcare personnel should use rubber dams if an aerosol-producing procedure is being performed to help minimize aerosol or spatter.

- Dental healthcare personnel may use a four-handed technique for controlling infection.

- Anti-retraction functions of handpieces may provide additional protection against cross-contamination.

- Dental healthcare personnel should prefer the use of high-volume evacuators. Dental healthcare personnel “should be aware that in certain situations, backflow could occur when using a saliva evacuator,” and “this backflow can be a potential source of cross contamination”.

- Dental healthcare personnel should use reabsorbable sutures (i.e., sutures that last 3–5 days in the oral cavity) to eliminate the need for a follow-up appointment.

- Dental healthcare personnel should minimize the use of a 3-in-1 syringe as this may create droplets due to forcible ejection of water/air.

- Disinfectants (hypochlorite, ethanol) in the handpiece and 3-in-1 syringe water supplies have been reported to reduce viral contaminants in splatter, but its action on human coronavirus is unknown.

**Steps after Suspected, Unintentional Exposure**
Follow CDC recommendations in the event of suspected unintentional exposure (e.g., unprotected direct contact with secretions or excretions from the patient).

- Aerosol-generating procedures should be scheduled as the last appointment of the day. For an aerosol-generating procedure performed without N-95 masks and only using surgical facemasks, regardless of disinfection procedures being effectively executed, subsequent patients, and DHCP are at moderate risk for COVID-19 infection and transmission. Given that asymptomatic patients may carry the virus, CDC suggests a 14-day quarantine. Alternatively, take all precautions to prevent transmission and require that the patient is tested for COVID-19 immediately after dental treatment; if positive, DHCP should quarantine for 14 days.

- Patients referred for COVID-19 testing should be given detailed instructions on when/where to go for testing, how to justify the need for testing to the testing facility visited, and how to contact the dental clinic to report test results (Algorithm 3). If a test is positive, the clinic needs to report the exposure to all patients treated after the infected patient.

**After Dental Care is Provided In-between Patients**

- Clean (PPE) with soap and water, or if visibly soiled, clean and disinfect reusable facial protective equipment (e.g., clinician and patient protective eyewear or face shields) between patients.

- Non-dedicated and non-disposable equipment (e.g., handpieces, dental X-ray equipment, dental chair, and light) should be disinfected according to the manufacturer’s instructions. Handpieces should be cleaned to remove debris, followed by heat sterilization after each patient.

- Routine cleaning and disinfection procedures (e.g., using cleaning water/air).

- Surfaces, such as door handles, chairs, desks, elevators, and bathrooms, should be cleaned and disinfected frequently.

**Postoperative Instructions for Patients**

- In light of the controversy regarding whether ibuprofen should be used for patients with a COVID-19 infection, it is recommended to use ibuprofen as normally indicated while managing any type of pain. For example, for the management of pulpal- and periapical-related dental pain and intraoral swelling in immunocompetent adults, it is recommended that nonsteroidal anti-inflammatory drugs (NSAIDs) in combination with acetaminophen (i.e., 400–600 mg ibuprofen plus 1,000 mg acetaminophen) can still be used.

- While treating patients with dental pain and intraoral swelling, dentists should determine whether definitive, conservative dental treatment (i.e., pulpotomy, pulpectomy, non-surgical root canal treatment, or incision for drainage of abscess) is available. The 2019 ADA clinical practice recommendations regarding the use of antibiotics are still applicable for immunocompetent adult patients with asymptomatic irreversible pulpitis with or without asymptomatic apical periodontitis, pulp necrosis and symptomatic apical periodontitis, or pulp necrosis and localized acute abscess, and should be referred to a dental specialist while determining the recommended course of action.

**Conclusion**
The novel coronavirus (2019-nCoV) is rapidly increasing in terms of cases and evidence of human-to-human transmission suggested that the virus was more contagious than SARS-CoV and MERS-CoV.25,27,29 Although dental clinics have been closed due the epidemic, a large number of emergency patients still go to the dental clinics for treatment. We have summarized the possible transmission routes of 2019-nCoV. We also reviewed several detailed practical strategies to block virus transmission to provide a reference for preventing the transmission of 2019-nCoV during dental diagnosis and treatment. Healthcare providers must keep
themselves updated about this evolving disease and provide adequate training to their staff.
