(Dated: September 8, 2015)

We analytically study the phase transitions between s-wave holographic insulator/superconductor and metal/superconductor. The problem is solved by the variational method for the Sturm-Liouville eigenvalue problem in the theory with dark matter sector of U(1)-gauge field coupled to the Maxwell field. Additionally in the probe limit we investigate the marginally stable modes of scalar perturbations in the AdS solitonic background, connected with magnetic field in the dark matter sector. We have found that even with dark matter sector the superconducting transition temperature $T_c$ is proportional to charge density $\rho$ in power $1/3$. This value seems to be strong coupling modification of the exponent $2/3$ known from the Bose - Einstein condensation of charged local pair bosons in narrow band superconductors. The holographic droplet solution is affected by the coupling to the dark matter. Interestingly in the probe limit the critical chemical potential increases with the decreasing coupling to dark matter making the condensation transition harder to appear.

I. INTRODUCTION

The gauge/gravity duality in the form of AdS/CFT correspondence \cite{1, 2} provides an interesting framework to study strong coupling effects in quantum many body $d$-dimensional systems \cite{3} by means of the $d + 1$ dimensional spacetime with the negative cosmological constant. In particular, this technique has been widely used to describe phase transitions from the normal or insulating to superconducting state. In the original work on 'building the holographic superconductor' \cite{4, 5}, the description of the single band s-wave superconductor was proposed. The scalar complex field with the appropriate potential has been incorporated into the theory of gravity and the condensation of its dual operator at finite temperature $T$, lower than the critical one $T_c$ was observed. The condensed operator has been identified with the superconducting order parameter. In the bulk, the temperature was introduced as the Hawking’s black hole one.

The aforementioned approach has been extended in many directions, taking into account the relevant aspects of the existing superconducting materials. For instance, the models of $d$-wave \cite{6} superconductivity have been considered, to shed some light on the strong coupling behaviour of the well known high temperature superconductors \cite{7}, which feature this symmetry of the order parameter. The spin triplet superconducting states of simple $p$-wave \cite{8} as well as the chiral $p_x \pm ip_y$ symmetry have also been elaborated in considerable details \cite{9}. In Refs. \cite{10} the multi-band superconducting systems have been studied in view of many materials in which the coexistence of different orbitals plays a crucial role, e.g., in MgB$_2$ \cite{11}, Sr$_2$RuO$_4$ \cite{12} or in heavy fermion superconductors \cite{13}. The description of these materials requires at least two hybridized orbitals which in the gravity approach translate into two scalar fields.

On the other hand, apart from the aforementioned studies of conductor/superconductor phase transitions, the holographic insulator/superconductor transitions attracted a great attention. Modification of the bulk gravity theory by considering the five-dimensional AdS soliton line element \cite{14} coupled to Maxwell gauge field and scalar one, allows for building a model of holographic insulator/superconductor phase transition at zero temperature \cite{15}. In gauge/gravity duality description, the AdS soliton is dual to a confined field theory with a mass gap, mimicking

an insulator phase \cite{10}. It was revealed that in the presence of a chemical potential in the solitonic background, the insulator/metal transition is of the second order. Namely, for the chemical potential greater than some critical value, the considered background turned out to be unstable and non-trivial hair emerged. This fact is interpreted as insulator/superconductor phase transitions.

In Refs. \cite{17, 18, 19, 20}, it was shown that the strength of various kinds of matter backreactions could generate new types of phase transitions. Marginally stable modes of scalar/vector perturbations in the AdS solitonic spacetime were studied in \cite{19, 20} to reveal the onset of the phase transition as well as to find the magnetic field effects on them. Among others, it was claimed that magnetic field made the phase transition harder to occur. The compatibility with the earlier investigations \cite{21} were also announced.

Recently, the influence of nonlinear electrodynamics on the holographic insulator/superconductor phase transitions was taken into account \cite{22, 23}, while the problem of \(p\)-wave symmetry of the transitions in question was treated in Ref. \cite{24, 25}. On the other hand, the analytical investigations tackling the phase transitions of this type, in Gauss-Bonnet gravity were discussed in \cite{26}.

Moreover, superconducting solutions in which the condensate was confined to a finite region and decayed rapidly outside during conductor/superconductor phase transitions, were examined. Both the vortex and the droplet models were constructed for \(s\)-wave type of superconductors \cite{27}. A non-Abelian droplet solutions emerging during insulator/superconductor phase transition in \(p\)-wave and \(p + ip\)-wave symmetry were studied in Ref. \cite{28}. It has been shown that in the case of Gauss-Bonnet background the coupling constant of the theory (like in \cite{26}) affects the transition in question.

Furthermore, the question of the possible matter configurations naturally appears in AdS spacetime. The problem of the strictly stationary Einstein-Maxwell spacetime with negative cosmological constant was treated in \cite{30}, while the simply connected Einstein-Maxwell-axion-dilaton spacetime with negative cosmological constant and arbitrary number of \(U(1)\)-gauge fields was examined in Ref. \cite{31}. It was revealed that the considered spacetimes could not allow for the existence of nontrivial configurations of complex scalar fields or form fields.

Motivated by the above problems as well as to provide continuity with our previous studies \cite{32, 33}, we address here the problem of phase transitions among insulator/superconductor and metal/superconductor for \(s\)-wave holographic superconductors in the theory in which \textit{dark matter} sector is coupled to the Standard Model. We shall look for the imprints of \textit{dark matter} sector in possible holographic experiments.

The importance of examinations of such kind of models goes back to the need of explanation of 511 keV gamma rays astrophysical observations made by Integral/SPI \cite{34} as well as the experiments showing the electron positron excess in galaxy, revealed by ATIC/PAMELA \cite{35, 36}. Their energies vary from a few GeV to a few TeV depending on the experiments. On the other hand, the new physics can explain the 3.6\(\sigma\) discrepancy between measured value of the muon anomalous magnetic moment and its prediction in the Standard Model \cite{37}. The other facet concerns the fact that dark matter model is subject to the key ingredient in early Universe, where the topological phase transition, giving rise to various topological defects, might have happened.

Our analysis will be addressed to the theory in which, apart from the gravitational action given by

\[
S_g = \int \sqrt{-g} \, d^5x \frac{1}{2\kappa^2} \left(R - 2\Lambda\right),
\]

where \(\kappa^2 = 8\pi G_5\) is five-dimensional gravitational constant, \(\Lambda = -6/L^2\) stands for the cosmological constant, while \(L\) is the radius of the AdS spacetime, we shall examine the Abelian-Higgs sector coupled to the second \(U(1)\)-gauge field

\[
S_m = \int \sqrt{-g} \, d^5x \left(-\frac{1}{4} F_{\mu\nu} F^{\mu\nu} - \nabla_{\mu} \psi - \imath q A_{\mu} \psi \right) \left(\nabla^\mu \psi - \imath q A^\mu \psi\right) - V(\psi) - \frac{1}{4} B_{\mu\nu} B^{\mu\nu} - \frac{\alpha}{4} F_{\mu\nu} F^{\mu\nu},
\]

where the scalar field potential satisfies \(V(\psi) = m^2 |\psi|^2 + \frac{\lambda}{2} |\psi|^4\). \(F_{\mu\nu} = 2\nabla_{[\mu} A_{\nu]}\) stands for the ordinary Maxwell field strength tensor, while the second \(U(1)\)-gauge field \(B_{\mu\nu}\) is given by \(B_{\mu\nu} = 2\nabla_{[\mu} B_{\nu]}\). Moreover, \(m, q\) represent a mass and a charge related to the scalar field \(\psi\). Here \(\alpha\) is a coupling constant between \(U(1)\) fields. The compatibility with the current observations establishes its order to \(10^{-3}\).

Within the above model the backreaction problems of the \textit{dark matter} sector on \(s\)-wave holographic superconductor was analyzed in Ref. \cite{32}. It was revealed that the \textit{dark matter} coupling constant is bigger the smaller is the critical temperature. The so-called retrograde condensation takes place for the negative value of the aforementioned constant. In Ref. \cite{33}, the nature of the condensate in external magnetic field and the behaviour of the critical field near the transition temperature were examined. The obtained upturn of the critical field constitutes the fingerprint of the strong coupling. In that study \(\alpha\) has been found to be limited to positive values.

The organization of the paper is as follows. In Sec.II we start by studying the \(s\)-wave holographic zero temperature insulator/superconductor phase transition using the solitonic AdS background. The chemical potential is the control
parameter of this phase transition. In Sec.III, black hole background taken as the gravity configuration allows for the analysis of the transition observed for $\mu > \mu_c$ from holographic metal at high temperatures ($T > T_c$) to holographic superconductor at temperatures below $T_c$. The effect of the dark matter sector on the insulator/superconductor transition of the droplet is studied in Sec.IV. We end the paper with summary and discussion of the obtained results in the light of variety of the existing metal/insulator and metal/superconductor transitions in condensed matter systems. We limit our analysis of the phase transitions to the probe limit.

II. PHASE TRANSITION INSULATOR/SUPERCONDUCTOR

In this section we analyze the model of s-wave holographic insulator/superconductor phase transition in five-dimensional spacetime, where the matter sector is coupled to another $U(1)$-gauge field, representing the dark matter sector. In the probe limit, we setup the considered model in the AdS soliton background \cite{14}, which line element is subject to the relation

$$ds^2 = -r^2 dt^2 + L^2 \frac{dr^2}{f(r)} + f(r) \ d\varphi^2 + r^2 \ (dx^2 + dy^2),$$

where $f(r) = r^2 - r_0^4/r^2$. The geometry resembles a cigar, if one gets rid of ($r$, $\varphi$)-coordinates, with a tip located at $r = r_0$. The AdS soliton solution is achieved by making two Wick rotations on a five-dimensional AdS Schwarzschild black hole line element. The asymptotic AdS spacetime tends to $R^{1,2} \times S^1$ topology near the boundary. A conical singularity at $r_0$ can be removed by the Scherk-Schwarz transformation of $\varphi$-coordinate, i.e., $\varphi \sim \varphi + \pi L/r_0$. Due to the compactification of $\varphi$-direction, the AdS solitonic background allows for a description of a three-dimensional field theory with a mass gap, which echoes an insulator in the condensed matter physics. The temperature in the solitonic background is equal to zero.

Without loss of generality we put $L = 1$ and for simplicity we assume that $A_t = \phi(r)$, $B_t = \eta(r)$ and $\psi = \psi(r)$. The underlying system of differential equations for scalar and gauge fields yields

$$\partial_r^2 \psi + \left( \frac{\partial_r f}{f} + \frac{3}{r} \right) \partial_r \psi + \left( \frac{q^2 \phi^2}{r^4 f^2} - \frac{m^2}{f} \right) \psi = 0,$$  

(4)

$$\partial_r^2 \phi + \left( \frac{\partial_r f}{f} + \frac{1}{r} \right) \partial_r \phi - \frac{2 q^2 \psi^2}{\alpha f} \phi = 0,$$  

(5)

$$\partial_r \eta = \frac{c_1}{r f} - \frac{\alpha}{2} \partial_r \phi,$$  

(6)

where we set $\alpha = 1 - \frac{4}{r_0^2}$ and $c_1$ as an integration constant.

Next we impose the boundary conditions on the adequate quantities. Namely, at the tip of the AdS soliton we demand that the solutions will be provided by

$$\psi = \psi_0 + \psi_1 (r - r_0) + \psi_2 (r - r_0)^2 + \ldots,$$  

(7)

$$\phi = \phi_0 + \phi_1 (r - r_0) + \phi_2 (r - r_0)^2 + \ldots,$$  

(8)

where $\psi_m$ and $\phi_m$, for the range $m = 0, 1, 2, \ldots$, are constants. Moreover, in order to achieve the finiteness of the considered quantities, one has to fulfill the Neumann-like boundary conditions ($\psi_1 = 0$ and $\phi_1 = 0$). Contrary to the AdS-black hole case, where at the event horizon $\phi$ is equal to zero, here it can acquire a non-zero value at the tip of the AdS soliton. On the other hand, near $r \to \infty$, we have the following behaviours:

$$\psi = \frac{\psi^-}{r^{\lambda_-}} + \frac{\psi^+}{r^{\lambda_+}}, \quad \phi = \mu - \frac{\rho}{r^2},$$  

(9)

where $\mu$ and $\rho$ stand for the chemical potential and charge density in the dual theory, while $\lambda_{\pm} = 2 \pm \sqrt{4 + m^2}$. The coefficients $\psi_{\pm}$ are responsible for the vacuum expectation values of the operators $< O_{\pm} >$ dual to the scalar field. One can impose the conditions that either $\psi^-$ or $\psi^+$ vanishes \cite{33}. In what follows we shall assume that $\psi^-$ vanishes and consider $\psi^+ = < O_1 >$ with $< O_1 >$ denoting the expectation value of the corresponding CFT operator.

It will be convenient to rewrite the above equations in terms of $z = r_0/r$ variable. They reduce to the forms

$$\psi'' + \left( \frac{f'}{f} - \frac{1}{z^4} \right) \psi' + \left( \frac{q^2 \phi^2}{z^2 f} - \frac{m^2 r_0^2}{z^4 f} \right) \psi = 0,$$  

(10)
\begin{align}
\phi'' + \left( \frac{f'}{f} + \frac{1}{z} \right) \phi' - \frac{2}{\alpha} \frac{q^2 \psi^2 \phi}{f z^4} &= 0, \\
\eta' &= -\frac{c_1}{z f} - \frac{\alpha}{2} \phi',
\end{align}

where the prime denotes the derivation with respect to \(z\)-coordinate.

A. Critical chemical potential

It was revealed in Ref.\[15\] that when the chemical potential exceeds a critical value, the condensation will set in. This state can be interpreted as a superconductor phase. In the case when \(\mu < \mu_c\) the scalar field \(\psi\) achieves value close to zero and the phase can be interpreted as the insulator. The system has a mass gap, which is connected with the confinement in \((2+1)\)-dimensional gauge theory via performing the Scherk-Schwarz compactification. In the light of these facts, the critical value of the chemical potential is the turning point in a superconductor phase transition.

For the chemical potential \(\mu = \mu_c\), the scalar field is very small \(\psi \sim 0\) and the equation (11) for the gauge field \(\phi\) reduces to the form

\[
\phi'' + \left( \frac{f'}{f} + \frac{1}{z} \right) \phi' \sim 0.
\]

The general solution of this equation can be easily found to read

\[
\phi(z) = d_1 + d_2 \log \frac{1}{1+ z^2},
\]

where \(d_1\) and \(d_2\) are integration constants.

In order to fulfill the assumed boundary conditions \[8\] at the tip \(z = 1\), we require \(d_2 = 0\). Thus \(\phi\) has the constant value \(\mu\), when \(\psi(z) = 0\). Moreover, from the equation \[10\], one obtains that in the considered case \(\rho = 0\). These results are in accord with the numerical analysis presented in \[13\].

By virtue of the above, as \(\mu \to \mu_c\), we have

\[
\psi'' + \left( \frac{f'}{f} - \frac{1}{z} \right) \psi' + \left( \frac{q^2 \mu^2}{z^2 f} - \frac{m^2 r_0^2}{z^4 f} \right) \psi = 0.
\]

By introducing a trial function \[28\] near the boundary \(z = 0\), in the form \(\psi(z) = \mathcal{O}_i \zeta^i F(z)\), where \(i = +\) or \(-\), and by imposing the boundary conditions \(F(0) = 1\) and \(F'(0) = 0\), the underlying equation can be brought to the following form

\[
(p(z) F'(z))^i - q(z) F(z) + \mu^2 r(z) F(z) = 0,
\]

where the various terms in the above relation are provided by

\[
p(z) = z^{2\lambda_i - 1} f,
q(z) = -z^{2\lambda_i - 2} \left( \frac{\lambda_i (\lambda_i - 1)}{z} \right) f' - \left( \frac{f'}{f} - \frac{1}{z} \right) \lambda_i f - \frac{m^2 r_0^2}{z^3},
\]

\[
r(z) = q^2 z^{2\lambda_i - 3}.
\]

According to the Sturm-Liouville eigenvalue problem, we can specify \(\mu^2\) as a spectral parameter and estimate its minimum eigenvalue by varying the following functional

\[
\mu^2 = \frac{\int_0^1 dz \left[ F'(z)^2 p(z) + q(z) F(z)^2 \right]}{\int_0^1 dz r(z) F^2(z)}.
\]

The trial function will be set in the form \(F(z) = 1 - a z^2\). Importantly, the critical value of the chemical potential is unaffected by the dark matter sector parameters. The value of the \(\mu^2\) in equation \[20\] depends on the parameter \(a\) entering the trial function. Changing \(a\) we find numerically minimal value of \(\mu^2\) for \(a = a_{\text{min}}\). Both \(a_{\text{min}}\) and \(\mu^2 = \mu^2(a_{\text{min}})\) depend on the parameters of the model - in particular \(m^2\). In Table \[9\] the critical chemical potential has been presented for a few typical values of \(m^2\) fulfilling the Breitenlohner-Freedman bound \(m^2 > -d^2/4 = \ldots\)
−16/4 required for the stability of the AdS_{d+1} spacetime. The same result was analytically obtained in s-wave holographic/superconductor phase transition studies in Einstein-Maxwell scalar theory \[25\], and is in accord with the numerical examinations provided in Ref.\[15\]. On the other hand, in Gauss-Bonnet gravity, for the transition in question, one observes the critical potential increase with the growth of curvature corrections, for the same mass of scalar field. For the fixed value of the strength of curvature corrections, with the increase of scalar field mass, the critical potential becomes larger \[27\].

| $\lambda_+$ | $m^2$ | $\mu_c$ | $\sigma_{min}$ |
|-----------|-------|--------|-------------|
| $-\frac{5}{2}$ | $-\frac{1}{4}$ | 1.890 | 0.330 |
| $-\frac{4}{3}$ | $-\frac{1}{2}$ | 2.398 | 0.371 |
| $-\frac{1}{2}$ | $-\frac{1}{4}$ | 2.903 | 0.407 |
| $\frac{3}{5}$ | 0 | 3.406 | 0.439 |

TABLE I: Values of the critical chemical potential together with a parameters minimizing the functional \[20\]. In all the above examples we put $q = 1.0$ and $r_0 = 1$. The numerical values of $m^2$ and $\lambda_+$ are chosen for illustration purposes. They obey the physical requirement that the masses $m^2$ do fulfill the Breitenlohner-Freedman bound $m^2 > -d^2/4 = -16/4$ required for the stability of the AdS_{d+1} spacetime.

B. Critical phenomena

In this subsection, we shall concentrate on studies of the critical exponent for condensation operator as well as on the mutual relations between the charge density $\rho$ and the chemical potential. The question we are asking here is how the order parameter of the superconductor \textit{i.e.} $< \mathcal{O}_i >$ and the charge density $\rho$ depend on the distance $(\mu - \mu_c)$. Having in mind the form of the scalar field $(\psi(z) = < \mathcal{O}_i > z^{\lambda_i} F(z)$, where $F(z)$ is the trial function introduced earlier) near the boundary $z = 0$, when $\mu \to \mu_c$, the relation for gauge $A_i = \phi(r)$ field can be rewritten as

$$\phi'' + \left( \frac{f'}{f} + \frac{1}{z} \right) \phi' - \frac{2q^2 r_0^2}{\alpha f} < \mathcal{O}_i >^2 z^{2\lambda_i-4} F^2(z) \phi = 0. \quad (21)$$

To proceed further, let us remind that for $\mu$ slightly above the critical value the condensation scalar operator $< \mathcal{O}_i >$ is very small. This enables us to seek the solution in the form

$$\phi(z) \sim \mu_c + < \mathcal{O}_i > \chi(z) + \ldots \quad (22)$$

In order to recover the previous result $\phi(z) = \mu$, we have to impose boundary condition $\chi(1) = 0$. On the other hand, close to the boundary $z = 0$ one expands the function $\chi(z) = \chi(0) + \chi'(0)z + \frac{1}{2}\chi''(0)z^2 + \ldots$, rewrites the relation \[9\] as

$$\phi(z) \simeq \mu - \rho z^2 \simeq \mu_c + < \mathcal{O}_i > \left( \chi(0) + \chi'(0)z + \frac{1}{2}\chi''(0)z^2 + \ldots \right), \quad (23)$$

Comparing the coefficients of the $z^0$ and $z^1$-terms, in the above equation, one obtains the relations

$$\mu - \mu_c \simeq < \mathcal{O}_i > \chi(0) \quad (24)$$

$$\chi(0) = 0. \quad (25)$$

Inserting the relation \[22\] into \[21\], one can easily find that $\chi(z)$ will satisfy the following equation:

$$\chi''(z) + \left( \frac{f'}{f} + \frac{1}{z} \right) \chi'(z) - \frac{2q^2 r_0^2}{\alpha f} z^{2\lambda_i-4} F^2(z) \mu_c < \mathcal{O}_i > - \frac{2q^2 r_0^2}{\alpha f} z^{2\lambda_i-4} F^2(z) < \mathcal{O}_i >^2 \chi(z) + \ldots = 0. \quad (26)$$

Close to $\mu_c$ the term quadratic in $< \mathcal{O}_i >$ is much smaller than the linear one and may be safely neglected leading to

$$\chi''(z) + \left( \frac{f'}{f} + \frac{1}{z} \right) \chi'(z) = \frac{2q^2 r_0^2}{\alpha f} z^{2\lambda_i-4} F^2(z) \mu_c < \mathcal{O}_i >. \quad (27)$$
In the next step, let us redefine \( \chi(z) \) function by the new one \( \xi(z) \) multiplied by the adequate factor

\[
\chi(z) = 2 \frac{<O_i> - \mu_c}{\tilde{\alpha}} \xi(z).
\] (28)

It remains to be checked if the new definition of \( \chi(z) \) enables us to get rid of the \( \tilde{\alpha} \) in the equation (27) and to extract the quantity \( <O_i> \). It can be inspected that \( \xi(z) \) will satisfy the following relation

\[
\xi'' + \left( \frac{f'}{f} + \frac{1}{z} \right) \xi' - \frac{q^2 r_0^2}{f} z^{2\lambda_i-4} F^2(z) = 0,
\] (29)

and consequently the scalar operators \( <O_i> \) imply

\[
<O_i> = \sqrt{\frac{(\mu - \mu_c) \tilde{\alpha}}{2 \mu_c \xi(0)}}.
\] (30)

In order to find \( \xi(0) \) it will be helpful to rewrite the equation (29) in the form

\[
\left( f z \xi' \right)' = q^2 r_0^2 z^{2\lambda_i-3} F^2(z).
\] (31)

Then, having in mind the fact that \( \xi'(1) = 0 \), leads to the conclusion that \( \xi(0) \) is provided by

\[
\xi(0) = c_1 - \int_0^1 \frac{dz}{f z} \left( c_2 + \int_1^2 dy q^2 r_0^2 y^{2\lambda_i-3} F^2(y) \right).
\] (32)

The integration constant \( c_1, c_2 \) are determined by the boundary conditions imposed on \( \chi(z) \)-function. We relegate their determination to the Appendix A.

On the other hand, the above relations reveal that the operators \( <O_i> \) yield

\[
<O_i> \sim \Gamma (\mu - \mu_c) \tilde{\alpha}^{\frac{1}{2}},
\] (33)

where the \( \Gamma \) factor contains information of the dependence on dark matter sector. The bigger \( \tilde{\alpha} \) (the smaller value of the \( \alpha \)-coupling constant we take) we consider, the greater factor one obtains.

Moreover, our analytical results show that the holographic s-wave insulator/superconductor phase transition represents the second order phase transition, with the critical exponent of the system attaining the mean-field value 1/2. The same conclusions were achieved in the case of of the ordinary s-wave holographic insulator/superconductor phase transition studies in Refs. [15, 20]. On the other hand, the same form of the dependence was also obtained in Gauss-Bonnet theory [27], confirming the previous numerical results [39, 40]. The Gauss-Bonnet coupling constant connected with the influence of curvature corrections, does enter in the multiplier factor of the scalar operators, but the critical value of the exponent takes the mean-field value.

Next, we find the dependence of the charge density \( \rho \) on the critical chemical potential. In order to calculate \( \rho \), we use (24) which implies \( \xi'(0) = 0 \) together with the previous requirement \( \xi(1) = 0 \) being subject to the boundary condition. Comparison of the adequate coefficients of \( z^2 \)-order in equation (23), gives the relation for the charge density in the following form

\[
\rho = -\frac{<O_i>}{2} \chi''(0).
\] (34)

In order to find \( \chi''(0) \) we rewrite equation (27) in the form which implies

\[
\left( f z \chi \right)' = \frac{2q^2 r_0^2}{\alpha} z^{2\lambda_i-3} F^2(z)\mu_c <O_i> = 0.
\] (35)

Integrating both sides of it and taking into account the aforementioned boundary conditions, one obtains

\[
\chi''(0) = \frac{\chi'(z)}{z} \bigg|_{z=0} = -2 <O_i> \frac{q^2 \mu_c}{\tilde{\alpha}} \int_0^1 dz z^{2\lambda_i-3} F^2(z).
\] (36)

Then, by virtue of the equations (30) and (34), having in mind the relation (30), one arrives at

\[
\rho = (\mu - \mu_c) \tilde{B},
\] (37)
where the quantity $\tilde{B}$ yields

$$\tilde{B} = -\frac{q^2}{2\xi(0)} \int_0^1 dz \ z^{2\lambda_i - 3} F^2(z).$$

(38)

In view of the above relations, the charge density is proportional to the difference $\Gamma_1 (\mu - \mu_c)$, where the factor is independent on $\lambda$ characterizing dark matter sector and accomplishes the ordinary dependence of the form $\rho \sim (\mu - \mu_c)$ achieved analytically in [20] and numerically in Refs. [17, 26]. Some typical values of \( B \) factor are presented in Table II. The dependence of the $\Gamma$ factor on the dark matter sector coupling $\alpha$ is depicted in Fig. 1.

In the case of Gauss-Bonnet gravity sector, the factor standing in front of $(\mu - \mu_c)$ is function of mass and Gauss-Bonnet coupling constant. However, the form of the linear dependence survives [27, 39].

| $\lambda_i$ | $m^2$ | $\mu_c$ | $\xi(0)$ | $\frac{\Gamma}{\sqrt{m^2}}$ | $\tilde{B}$ |
|------------|--------|--------|---------|-----------------|---------|
| $\frac{1}{2}$ | $-\frac{12}{7}$ | 1.890 | 0.081 | 1.801 | 1.329 |
| $\frac{3}{2}$ | $-\frac{12}{7}$ | 2.398 | 0.062 | 1.823 | 1.144 |
| $\frac{5}{2}$ | $-\frac{7}{2}$ | 2.903 | 0.049 | 1.863 | 1.029 |
| $\frac{7}{2}$ | 0 | 3.406 | 0.040 | 1.913 | 0.948 |

TABLE II: Values of the prefactors for the condensate and charge density. In all above examples $q = 1.0$ and trial function was of the form $F = 1 - az^2$.

III. HOLOGRAPHIC METAL/SUPERCONDUCTOR PHASE TRANSITION

In this section we shall scrutinize the problem of holographic s-wave metal/superconductor phase transition at low temperatures provided by the black hole background. The problem of s-wave holographic superconductor with dark matter sector in the context of the backreaction of matter fields on the gravitational background was investigated in [32], where the critical temperature was found. On the other hand, for n-dimensional gravitational background, the expectation value of the scalar operator and the influence of magnetic field on the holographic superconductor was analyzed [33]. For the completeness of the investigations, using quite different methods, we elaborate the dependence of the critical temperature and the scalar operator on the presence of the dark matter sector.

To commence with, one considers the background of five-dimensional black hole given by the line element

$$ds^2 = -g(r) dt^2 + \frac{dr^2}{g(r)} + \frac{r^2}{L^2} (dx^2 + dy^2 + dz^2),$$

(39)

where $g(r) = r^2/L^2 - r_+^4/r^2 L^2$. The Hawking temperature for the black hole has the form $T_{BH} = r_+ / \pi$. In $z$-coordinate the equations of motion imply

$$\psi'' + \left( \frac{g'}{g} - \frac{1}{z} \right) \psi' + \left( \frac{q^2 \phi^2}{g^2} - \frac{m^2}{g} \right) \frac{r_+^2}{z^4} \psi = 0;$$

(40)

$$\phi'' - \frac{1}{z} \phi' - \frac{2q^2}{\alpha} \psi \phi \frac{r_+^2}{z^4} = 0;$$

(41)

$$\eta' = -\frac{d_1 z}{r_+^2} - \frac{\alpha}{2} \phi',$$

(42)

where the prime denotes the derivation with respect to $z$-coordinate. In the following, as in the preceding sections, we set $L = 1$. In order to solve the above equations we need to impose the adequate boundary conditions. At the black hole horizon $z = 1$, it is required that $\phi(1) = 0$ and $\psi(1)$ should be finite. The first requirement is needed for the $U(1)$-gauge field to have the finite form, the second one exhibits that the black hole has a scalar hair on the event horizon.

When the temperature $T$ tends to the critical value $T_c$ from below, the condensation approaches zero, $\psi \to 0$. In this limit we write the equation for $\phi$ field as

$$\phi'' - \frac{1}{z} \phi' \simeq 0.$$  

(43)
Its general solution is of the form \( \phi(z) = c_1 + c_2 z^2 \), which together with the aforementioned boundary condition at the horizon leads to \( \phi(z) = c_1(1 - z^2) \). Then, having in mind that near the boundary of the bulk the fields behave as

\[
\phi \rightarrow \mu - \frac{\rho}{r_+^2} = \mu - \rho z^2/r_+^2, \quad \psi \rightarrow \frac{\psi^-}{r_+^2} + \frac{\psi^+}{r_+^2},
\]

one arrives at the conclusion that near the critical temperature the \( A_t \) gauge field component will behave as \( \phi \sim \lambda r_+ (1 - z^2) \), where we have denoted by \( \lambda = \rho/r_+^2 \). \( \mu \) and \( \rho \) have the same interpretation as in the preceding sections, i.e., denote the chemical potential and the charge density, respectively. Moreover, \( \Delta_\pm \) have the same values as in Sec.II, but in order to distinguish the nature of the phase transition, we set the new notation for the old quantity.

In what follows we concentrate on the \( \Delta = \Delta_+ \), but in order to distinguish the nature of the phase transition, we set the new notation for the old quantity. In what follows we concentrate on the \( \Delta = \Delta_+ \), but in order to distinguish.

On the other hand, the scalar field \( \psi \) can be cast near the boundary in the form

\[
\psi \big|_{z \to 0} \approx <C> \frac{z^\Delta}{r_+^2} G(z),
\]

where, we set \( G(0) = 1, \ G'(0) = 0 \). Inserting this expression into the equation \( 40 \) and using \( \phi = \lambda r_+ (1 - z^2) \) one finds the scalar field equation of motion, which can be easily rewritten as the Sturm-Liouville eigenvalue problem

\[
(\mathcal{P}(z) G'(z))^\prime - \mathcal{Q}(z) G(z) + \lambda^2 \mathcal{R}(z) G(z) = 0,
\]

where one has defined the quantities

\[
\mathcal{P} = z^{2\Delta - 1} g, \\
\mathcal{Q} = -\Delta(\Delta - 1) g z^{2\Delta - 3} - \left( \frac{g'}{g} - \frac{1}{z} \right) \Delta z^{2\Delta - 2} g + m^2 r_+^2 z^{2\Delta - 5}, \\
\mathcal{R} = \frac{z^{2\Delta - 5}}{g} r_+^4 (1 - z^2)^2 q^2.
\]

The minimum value of \( \lambda^2 \) can be found from variation of the functional given by

\[
\lambda^2 = \int_0^1 dz \left[ G'(z)^2 \mathcal{P}(z) + \mathcal{Q}(z) G^2(z) \right] / \int_0^1 dz \mathcal{R}(z) G^2(z),
\]

where the trial function is assumed to be given by \( G(z) = 1 - a z^2 \). Note that in the variable \( z \), the function \( g(z) = r_+^2 (1/z^2 - z^2) \) and the value of event horizon radius \( r_+ \) factors out of the expression for \( \lambda^2 \) making it independent on \( T_{BH} \). Because of that and the fact that the analysis is valid close to the transition temperature \( T_c \sim T_{BH} \), one readily finds that

\[
T_c = \rho^{1/3} \left( \frac{1}{\pi^3 \lambda_{\text{min}}} \right)^{1/3}.
\]

It is important to note that the value \( \lambda_{\text{min}} \) results from the variation of Sturm-Liouville functional \( [51] \). Holographic superconductors with different values of \( \rho \) are characterized by different transition temperatures. This reminds the charge carrier concentration dependence of the local pairing superconductors \( [11] \). However, the charge density dependence of the critical temperature \( T_c \propto \rho^{1/3} \) found here markedly differs from the known dependence \( T_c \propto n^{2/3} \) for the Bose-Einstein condensation of the low density \( n \) superconductors with local pairs of charged hard core bosons \( [11] \). Whether the difference is the hallmark of the strong coupling behavior remains to be seen. In fact it has been suggested \( [3] \) that the condensation transition in holographic models is closer to the Bose-Einstein condensation than BCS-like symmetry breaking phase transition. It has to be reminded that the critical temperature does not depend on the carrier concentration \( n \) in the standard weak coupling superconductors described by the BCS theory. Instead it depends on the density of states at the Fermi level \( [42] \).

It can be observed that the critical temperature does not depend on the dark matter sector. This conclusion is in accord with our previous studies \( [32] \), where it was revealed that the backreaction effects introduce the dependence of
$T_c$ on the dark matter sector. In the case under consideration we restrict our investigations to the probe limit case, therefore no influence is spotted.

In the Table III we have presented the results of the calculation of the superconducting transition temperature assuming the charge density $\rho = 1$. The presented theory is valid for arbitrary allowed values of $m^2$, but for illustration we have chosen some exemplary values of it and calculated $\lambda^2$ and the critical temperature $T_c$. Both of these parameters are presented in the Table III together with the value of the parameter $a$, which minimizes the functional $\mathcal{F}$.

A. Condensation values

In this subsection our main task will be to find the influence of the dark matter sector field on the condensation operator. Near the critical temperature, the equation for gauge field can be rewritten as

$$\phi'' - \frac{\phi'}{z} = \frac{2 q^2 r^2_+}{\tilde{\alpha} g} z^{2\Delta-4} G^2(z) A, \quad (53)$$

where we have denoted $A = <C>^2/r^{2\Delta}_+$. Having in mind the fact that near the critical temperature the $A$ quantity is small, one expands $\phi$ near $z \to 0$. On this account, we can write the following:

$$\frac{\phi}{r^+_z} = \lambda (1 - z^2) + A \chi(z) + \ldots. \quad (54)$$

In the next step, comparing the coefficients in $z^2$-order terms, we reveal that

$$\frac{\rho}{r^+_z} = \lambda - \frac{A}{2} \chi''(0). \quad (55)$$

On the other hand, considering the relation (54) and the equation of motion for $\phi$ field, we get

$$\chi'' = \frac{\chi'}{z} = \frac{2 \lambda q^2 r^2_+}{\tilde{\alpha} f} (1 - z^2) z^{2\Delta-4} G^2(z). \quad (56)$$

Consequently, proceeding as in the last section, it can be verified that the following is satisfied

$$\chi''(0) = \frac{\chi'(z)}{z} \bigg|_{z \to 0} = -2 \lambda \int_0^1 dz \frac{q^2 r^2_+}{\tilde{\alpha} f} (1 - z^2) z^{2\Delta-5} G^2(z). \quad (57)$$

On evaluating the expression for $A$, in the case when $T \to T_c$, the condensation operator in question is provided by

$$<C> = \sqrt{\frac{\tilde{\alpha}}{B}} (\pi T_c)^\Delta \sqrt{1 - \frac{T}{T_c}} = \sqrt{\alpha} <C>_{no dark sect}, \quad (58)$$

where $<C>_{no dark sect}$ we denoted the value in the theory without dark matter sector. The term $B$ is given by the relation

$$B = 2 \int_0^1 dz \frac{q^2 r^2_+}{g} (1 - z^2) z^{2\Delta-5} G^2(z). \quad (59)$$

One can see that the condensation operator depends on the $\alpha$ constant coupling of the dark matter sector. The bigger is the $\alpha$-coupling, the easier condensation forms. From the point of view of the AdS/CFT correspondence, the operator in question can be interpreted as the operator for pairing mechanism. The bigger expectation value it achieves, the harder condensation occurs. In order to better understand the dependence of the condensate on the dark matter sector we factor out its dependence on the rest of the parameters in the following way:

$$<C>_{norm} = \frac{<C>}{T_c^\Delta} \equiv \sqrt{\tilde{\alpha}}\tilde{C}\sqrt{1 - \frac{T}{T_c}}, \quad (60)$$

where $\tilde{C} \equiv \sqrt{\pi}^{\Delta}$ and $<C>_{norm}$ represent renormalized value of the condensate. The factor $\tilde{C}$ depends on all the remaining parameters (except temperature) and its typical values are presented in Table III. These facts can potentially constitute the way of determining the dark matter sector in future 'possible' superconductor experiments.

We remark that, in the case of Gauss-Bonnet theory [44], the value of $<C>$ is dependent on the higher curvature term corrections. When it grows, the value of the operator also increases. This conclusion is in agreement with the previous studies (see, e.g., [39] and references therein).
TABLE III: Calculated values of the prefactors of $\lambda^2$ minimizing the functional (51), the superconducting transition temperature of the superconductor with charge denisity $\rho = 1$ and the prefactor $\tilde{C}$ defined in Eq. (60). In all the above examples we assumed $q = 1.0$ and selected the trial function as $G = 1 - a z^2$. We also provide the parameter $a$ minimizing the functional (51).

| $\Delta$ | $m^2$ | $\chi^2$ | $a_{\text{min}}$ | $T_c(\rho = 1)$ | $\tilde{C}$ |
|----------|-------|----------|-----------------|----------------|-------------|
| $\frac{5}{2}$ | $-\frac{15}{2}$ | 9.586 | 0.619 | 0.218 | 55.67 |
| $\frac{3}{2}$ | $-\frac{12}{2}$ | 18.22 | 0.721 | 0.196 | 137.8 |
| $\frac{1}{2}$ | $-\frac{5}{2}$ | 30.50 | 0.797 | 0.180 | 326.7 |
| $\frac{3}{2}$ | 0 | 46.89 | 0.853 | 0.168 | 748.3 |

IV. HOLOGRAPHIC DROPLET IN S-WAVE INSULATOR/SUPERCONDUCTOR PHASE TRANSITION

The term superconducting droplet refers to the solutions that are confined in space and rapidly decay at large distances. This happens if the studied superconductor is exposed to strong external magnetic field. The size of the confining region diminishes with the increase of the magnetic field. In this section we shall investigate the onset of the transition by studying the marginally stable modes of scalar perturbations. It has been shown earlier [19, 20, 45] that in the holographic approach the marginally stable modes signal the appearance of the insulator-superconductor transition.

Here we are interested in the insulator - superconductor phase transition in the AdS solitonic background coupled to the dark matter sector. The presence of the magnetic field introduced via dark matter potential enables us to examine the droplet solution via the aforementioned technique.

It turned out that the quasi-normal modes (QNMs) technique occurred as a method of examining stability of a spacetime background [46]. In the case when the imaginary part of QNMs is negative, the modes decrease in time and result in disappearance of perturbations (background is stable against perturbations). On the other hand, when imaginary part is positive, the background is unstable against the perturbations in question. The marginally stable modes are the modes which frequencies go to zero ($\omega = 0$) near the critical point of the phase transition. Their appearance thus signals the phase transitions [21, 22].

To commence with, we consider AdS soliton metric, taking into account symmetry of the problem in question and rewrite the line element used in Sec.II in the following coordinates ($t, r, \tilde{\rho}, \varphi, \theta$) as

$$ds^2 = -r^2 dt^2 + \frac{dr^2}{f(r)} + f(r) d\varphi^2 + r^2 (d\tilde{\rho}^2 + \tilde{\rho}^2 d\theta^2),$$

(61)

Further, we assume the existence, in addition to a constant chemical potential bounded with $A_t$ gauge field component, the $B_\theta$ potential which corresponds to the dark matter gauge field and is proportional to the constant value of magnetic field $B$

$$A_t = \mu, \quad B_\theta = \frac{1}{2} B \tilde{\rho}^2.$$  

(62)

The above ansatz stems from the fact that one considers gauge sector close to the critical point of the phase transition, i.e., $\mu \sim \mu_c$ and $\psi \sim 0$, as well as, the implementation of the polar coordinates in order to envisage the symmetry of the problem in question [20].

Having in mind the exact form of $B_\theta$, given by the above relation, we calculate from equation of motion

$$\nabla_\mu B^{\mu\nu} + \frac{\alpha}{2} \nabla_\mu F^{\mu\nu} = 0,$$

(63)

the $A_\theta$ component, which yields

$$A_\theta = \frac{D_1 r \tilde{\rho}^2}{\alpha} - \frac{B}{\alpha} \tilde{\rho}^2 + D_2.$$  

(64)

$D_1$ and $D_2$ are integration constants. To proceed further, we assume $A_\theta$ to be the function of $\tilde{\rho}$ only, which implies that $D_1$ and $D_2$ have to be equal zero. Our studies are devoted to the probe limit, i.e., the $U(1)$-gauge fields and scalar one do not backreact on the AdS soliton background metric. Without the condensate (i.e. for $\psi = 0$) the
solution of the equations of motion for the $A$ gauge field components are given by the $A_{\theta} = -\frac{B}{\rho^2}$ and $A_{t} = \mu$. We are interested in finding the solution of $\psi$ equation close to the critical chemical potential $\mu \sim \mu_{c}$, where the value of the scalar field reaches nearly zero. It implies that one can treat $\psi$ field as a probe into the background consisting of AdS Schwarzschild soliton with constant electric and magnetic field.

The equation describing $\psi$ field yields

$$ \nabla_{\mu} \nabla^{\mu} \psi - q^{2} A_{\mu} A^{\mu} \psi - m^{2} \psi = 0. \quad (65) $$

By virtue of the above, the explicit form of the equation for $\psi$ field may be written as

$$ \partial^{2}_{\rho} \psi + \left( \frac{\partial f}{r} + \frac{3}{r} \right) \partial_{r} \psi + \frac{1}{f^{2}} \partial^{2}_{r} \psi - \frac{1}{r^{2} f} \partial^{2}_{r} \psi + \frac{1}{r^{2} f} \frac{1}{\rho} \partial_{\rho} (\rho \partial_{\rho} \psi) \quad (66) $$

$$ + \frac{1}{r^{2} f} \left( q^2 \mu^2 - m^2 r^2 - \frac{q^2 B^2 \rho^2}{\alpha^2} \right) \psi = 0. $$

In order to solve the above equation we choose an ansatz for $\psi$

$$ \psi = F(r, t) H(\varphi) U(\rho). \quad (67) $$

This form enables us to separate variables. After a simple algebra we arrive at the following set of equations

$$ \partial^{2}_{\rho} F + \left( \frac{3}{r} + \frac{\partial f}{f} \right) \partial_{r} F - \frac{1}{r^{2} f} \partial^{2}_{r} F + \frac{1}{r^{2} f} \left( \frac{q^2 \mu^2}{r^2} - \frac{m^2 r^2}{f} - \frac{\lambda^2}{f} \right) F = 0, \quad (68) $$

$$ \frac{\partial^{2} H}{H} = -\lambda^2, \quad (69) $$

$$ \frac{1}{\rho} \partial_{\rho} \left( \rho \partial_{\rho} U \right) - \frac{q^2 B^2 \rho^2}{\alpha^2} U = -k^2 U. \quad (70) $$

From periodicity property $H(\varphi) = H(\varphi + \pi / L)$ of $H(\varphi)$ we identify that $\lambda = 2 \ rho_0 n / L$, where $n \in Z$. In what follows without loss of the generality we set $\rho_0 = 1$ and $L = 1$ what leads to $\lambda = 2 n$. We expect that the lowest mode will be first to condense and result in the most stable solution.

The equation for $U(\rho)$ is a two-dimensional harmonic oscillator one. In order to solve it we recall that the function $U(\rho)$ should satisfy the boundary conditions $U(\rho \to \infty) = 0$. It is possible to investigate such kind of differential equation by Frobenius method. The customary procedure is first to factor out the behaviour of the relevant solutions at infinity by setting

$$ U(\rho) = e^{-\Lambda \rho^2 / 2} D(\rho), \quad (71) $$

which results in Hermite’a type of equation. Inserting \ref{71} into the underlying equation, we obtain the expected type of the differential solution if the condition

$$ \lambda^2 = \frac{q^2 B^2}{\alpha^2}. \quad (72) $$

is satisfied. Then, the resulting equation yields

$$ \frac{1}{\rho} \partial_{\rho} \left( \rho \partial_{\rho} D \right) - 2 \Lambda \rho \partial_{\rho} D + (k^2 - 2 \Lambda) D = 0. \quad (73) $$

In order to find the exact form of $D(\rho)$, one sets $D(\rho) = \sum_{k=0}^{\infty} a_n \rho^{k+i}$ (see, e.g., \ref{47}).

Note that $D(\rho) = const$ is the well know lowest energy solution of the harmonic oscillator. It leads to the condition

$$ k^2 = 2 \Lambda = \frac{2 q B}{\alpha}. \quad (74) $$

Equation \ref{71} shows that in the presence of magnetic field the superconducting region is confined in space. For the chosen solution $D(\rho) = const$ it forms a droplet \ref{48} of radius

$$ < \rho > = \frac{\int d\rho \rho U(\rho)}{\int d\rho U(\rho)} = \frac{1}{\sqrt{2\pi \Lambda}} = \frac{\sqrt{\alpha}}{4 \pi q B}. \quad (75) $$
In the field theory it corresponds to the condensation in the lowest Landau level [12]. As far as the time dependence of the $F(r, t)$ is concerned, we substitute it in the form $F(r, t) = e^{-i\omega t} R(r)$. The requirement concerning marginally stable modes leads to the condition $\omega = 0$. Redefining the coordinates as $z = r_+/r$ enables to arrive at the equation given by

$$\partial_z^2 R(z) + \left( \frac{\partial_z f}{f} - \frac{1}{z} \right) \partial_z R(z) + \frac{1}{z^2 f} \left( q^2 \mu^2 - \frac{2 B q}{\alpha} - \frac{m^2}{z^2} - \frac{4 n^2}{z^2 f} \right) R(z) = 0. \quad (76)$$

To solve it close to $\mu_c$ when the field $\psi \approx 0$ we introduce a correction function $\Theta(z)$ in the form

$$R(z) \big|_{\psi \to 0} < O_1 > z^{\lambda_1} \Theta(z), \quad (77)$$

with the boundary conditions $\Theta(0) = 1$ and $\Theta'(0) = 0$. After some algebra, the resulting equation can be converted into the standard Sturm-Liouville eigenvalue equation, which can be rewritten as

$$\partial_z \left( a(z) \Theta' \right) - b(z) \Theta + \delta^2 c(z) \Theta = 0, \quad (78)$$

where $\delta^2 = q^2 \mu_c^2 - 2 q B / \alpha$ and the remaining quantities are defined by the relations

$$a(z) = f z^{2\lambda_1-1}, \quad (79)$$

$$b(z) = -f z^{2\lambda_1-1} \left( \frac{\lambda_1 (\lambda_1-1)}{z^2} + \left( \frac{\partial_z f}{f} - \frac{1}{z} \right) \frac{\lambda_1}{z} - \frac{1}{z^4 f} \left( m^2 + 4 n^2 \right) \right), \quad (80)$$

$$c(z) = z^{2\lambda_1-3}. \quad (81)$$

The eigenvalues of $\delta^2$ can be found by the method of minimizing the functional

$$\delta^2 = q^2 \mu_c^2 - 2 q B / \alpha = \int_0^1 dz \left( \Theta'(z)^2 a(z) + b(z) \Theta(z)^2 \right) - \int_0^1 dz \left( c(z) \Theta^2(z) \right). \quad (82)$$

In order to estimate $\delta^2$, we choose function $\Theta(z) = 1 - a z^2$. Minimization of the functional provides an estimation of the value of $\delta$ which depends on $m^2$ and $n$, resulting from the periodicity property of $H(\varphi)$. The above relation between $\delta^2$, critical chemical potential $\mu_c$ can be rewritten as

$$\mu_c = \sqrt{\delta^2 + \frac{2 a B}{q}}. \quad (83)$$

It follows that $\mu_c$ depends on the coupling to the dark matter sector $\alpha$. Interestingly, for constant magnetic field $B$ the critical chemical potential diverges for $\alpha \to 0$. It means that at the constant magnetic field the condensation is harder to occur for smaller values of $\alpha$. However, one has to remember that the zero value of $\alpha$ is not allowed, as simultaneously one has to take $B = 0$, so without dark matter field the standard relation, valid for zero magnetic field [29] $\delta^2 = q^2 \mu_c^2$, is recovered. The increase of the magnetic field causes the increase of $\mu_c$, which in turn eventuates in the harder condensation. The aforementioned behaviour is depicted in Fig.2 for two values of the magnetic field. The discussed increase of $\mu_c$ for small $\alpha$ is clearly visible both for $B = 0.1$ and for $B = 1$.

V. DISCUSSION AND CONCLUSION

The main aim of our paper is to find the quantitative or at least qualitative imprints of the dark matter sector on the properties of s-wave holographic superconductor phase transitions. The unordinary features might constitute the possible hints for future experiments testing the considered model of dark matter. In the model in question, apart from the electromagnetic matter field we have taken into account the dark matter sector described by another $U(1)$-gauge field, bounded with the Maxwell field by the coupling constant $\alpha$.

The models where dark matter is a part of a larger sector which interacts with visible matter were successsfully implemented as the possible explanations of various astrophysical anomalous observations like the excess of electrons in Galaxy having energies of a few GeV and TeV, gamma rays of 511 keV [52]. There were also efforts to find new physics explaining the anomalous muon magnetic moment, possible implication for parity violation, rare meson decays [50], as well as, to provide some implications of boson and dark boson mixing for high energy experiments [57]. This
problem is of a great importance especially in the light of the latest claim of nongravitational interactions of dark matter in colliding galaxy clusters [58], which can disfavor some extensions of the Standard Model.

In the paper we have discussed analytically various phase transitions toward the s-wave holographic superconductor in the probe limit. Our results for \( \alpha = 0 \) agree with the previous numerical and analytical studies of holographic superconductor transitions. The coupling between ordinary and dark matter changes the values of the parameters at the transition, however, only quantitatively for s-wave superconductors.

To make contact between transitions studied here and those known in the condensed matter systems, let us recall some basic facts from the latter field of research. In the condensed matter systems there exist a number of metal/insulator transitions. They differ by the role played by the interactions between carriers and the lack of periodicity of the underlying crystal lattice. The metal/insulator transition may appear when the carriers strongly interact with each other. On the physical grounds it can be argued that in such strongly correlated system the electron movement is hindered by the repulsive interactions and as a result, the insulator may form. The literature on the Mott-Hubbard metal/insulator transition [50, 51] is vast and the transition itself is still not fully understood [52]. The other interesting transition appears in the system which is not translationally invariant. The transition is driven with each other. On the physical grounds it can be argued that in such strongly correlated system the electron

metal/insulator transitions. They differ by the role played by the interactions between carriers and the lack of periodicity of the underlying crystal lattice. On the physical grounds it can be argued that in such strongly correlated system the electron movement is hindered by the repulsive interactions and as a result, the insulator may form. The literature on the Mott-Hubbard metal/insulator transition [50, 51] is vast and the transition itself is still not fully understood [52]. The other interesting transition appears in the system which is not translationally invariant. The transition is driven

Our study is restricted to the system which is periodic on the boundary and the insulator/metal transition we study should be related to the Mott-Hubbard one. The sequel of the transitions we are discussing, i.e., insulator/superconductor at zero temperature and metal/superconductor at higher temperatures are realized in high temperature cuprate and iron superconductors with the increase of the carrier doping. The \( T = 0 \) insulator/superconductor transition is an analog of the Hawking - Page like soliton-black hole transition. In real superconductors increase of charge density beyond the upper limit induces (at low temperatures) a reverse superconductor to metal transition, which seemingly has not been hitherto found in holographic analogy.

Treating \( \mu^2 \) as a spectral parameter we analyze the behaviour of it in s-wave insulator/superconductor phase transition. We did not observe the influence of the dark matter sector on this quantity. The charge density is proportional to the difference \( (\mu - \mu_c) \), and also does not depend on the dark matter sector in the probe limit. In the case of the scalar operator it was revealed that it is proportional to \( (\mu - \mu_c)^{1/2} \) and represents the second order phase transition. The critical exponent of the considered system has the mean-field value, while the proportionality factor is subject to dark matter coupling constant dependence. The smaller value of \( \alpha \) is considered, the greater factor one obtains, i.e., the harder condensation happens (it will also be the case in s-wave holographic metal/superconductor phase transition).

The same conclusions were drawn studying s-wave type of the transition in question in Gauss-Bonnet theory. The Gauss-Bonnet coupling which envisages the influence of higher curvature corrections, does influence the considered factor and the form of linear dependence survives.

In the case of holographic metal/superconductor phase transition, the critical temperature does not depend on dark matter sector. The conclusion is in accord with our previous studies [32], where it was shown that the backreaction effects introduced the dependence of \( T_c \) on dark matter sector. On the contrary, the condensation operator reveals a linear dependence on the \( \alpha \)-coupling constant. The bigger dark matter coupling constant one considers, the easier condensation forms.

Examining s-wave droplet insulator/superconductor phase transition, it was found that the chemical potential and magnetic field were bounded with the linear dependence. Not only does the magnetic field influence the condensation but also the coupling constant of dark matter sector does this. The increase of the magnetic field causes the increase of \( \mu_c \), which eventuates in the harder condensation. For the fixed value of the magnetic field, it happens that the smaller value of the dark matter sector coupling constant one chooses, the harder condensation takes place. A very similar behaviour was envisaged in the holographic droplet in p-wave insulator/superconductor phase transition case.

To conclude, we remark that there are some points which are in contrast to the ordinary behaviour (without dark matter sector) during the aforementioned phase transitions, which may constitute indicators for the future experiments for detecting dark matter and elucidating its nature. Testing s-wave holographic superconductors with dark matter sector is the only tip of the iceberg and some more complicated models like p-wave or \( \mu_s + i\mu_p \) should be taken into account. We hope to investigate these problems elsewhere. Our preliminary calculations show the stronger modifications of the p-wave superconductor characteristics by the dark matter coupling \( \alpha \).

Appendix A: Integration constants in Eq. (32)

Equation (32) provides formal solution of the differential equation (29) and contains two integration constants. The value of \( \xi(0) \) enters the prefactors \( \Gamma \) and \( \hat{B} \) of the dependence of the condensation operator \( \left< \mathcal{O}_i \right> \) and the density
\( \rho \) on the chemical potential.

To find numerical values of the coefficients \( \Gamma \) and \( \tilde{B} \) we note that the integrals entering equation (32) still contain terms singular at \( z = 1 \) which have to be eliminated by the proper choice of constants. To this end we take \( F(y) = 1 - ay^2 \) and for numerical evaluation of the constants use the values of \( a = a_{min} \) which minimize the functional (20) for \( \mu^2 \). Evaluating the (non-singular) integral over \( y \) in Eq. (32) leads to

\[
q^2 r_0^2 \int_1^\infty dy \; y^{2\lambda_i-3} F^2(y) = q^2 r_0^2 \left [ \left( y^{2\lambda_i} \left( -\frac{a}{\lambda_i} + \frac{1}{2(\lambda_j - 1)z^2} + \frac{a^2 y^2}{2(\lambda_i + 1)} \right) \right) \right ]^z
\]

Inserting the above result denoted as \( R(z) \) into (32) and performing the integral over \( z \) one gets

\[
\xi(0) = c_1 - \frac{1}{\lambda_i - 1} \left [ \frac{c_2}{q^2 r_0^2} (\log(1 + z^2) - \log(1 - z^2)) + q^2 r_0^2 W(z) \right ]^0 \tag{A2}
\]

where we have denoted

\[
W(z) = \left[ 2\lambda_i(1 + a^2(\lambda_i - 1) + \lambda_i)z^{2\lambda_i+4} 2F_1(1, 1 + \lambda_i; 2 + \lambda_i, z^4) - (2 + \lambda_i)(-2z^{2\lambda_i}(\lambda_i + 1) + 4\lambda_i z^{2\lambda_i+2} 2F_1(1, 1 + \lambda_i; \lambda_i, z^4) - (2z^{2\lambda_i}(\lambda_i + 1) - 2a(\lambda_i^2 - 1)) \log(1 - z^2) + (2a + \lambda_i + a^2\lambda_i + \lambda_i^2 + 2a\lambda_i^2 - a^2\lambda_i^2) \log(1 + z^2) \right ]/[8(\lambda_i - 1)\lambda_i(\lambda_i + 1)(\lambda_i + 2)] \tag{A3}
\]

Here \( 2F_1(a, b; c, z) \) is the hypergeometric function [43]. For the special values of parameters with \( c = a + b \), as in the above expression, it diverges for \( z \to 1 \) and takes the form [43]

\[
\lim_{z \to 1} 2F_1(a, b; a + b, z) = -\frac{\Gamma(a + b)}{\Gamma(a)\Gamma(b)} \log(1 - z). \tag{A4}
\]

It is easy to check that \( W(0) = 0 \). On the other hand the boundary condition \( \xi(1) = 0 \) requires

\[
c_2 = -\frac{q^2 r_0^2}{\lambda_i - 1} \tag{A5}
\]

and

\[
c_1 = -\frac{q^2 r_0^2}{\lambda_i - 1} \left[ \frac{\log 2}{4(\lambda_i - 1)} + \frac{1}{4\lambda_i(\lambda_i - 1)} + \left( \frac{a}{4\lambda_i(\lambda_i + 2)} - \frac{a^2}{4(\lambda_i + 1)(\lambda_i + 2)} - \frac{1}{8(\lambda_i - 1)(\lambda_i + 2)} \right) \log 2 \right ] \tag{A6}
\]

Introducing the obtained results into the equation (24), one gets the required formula

\[
< \mathcal{O}_i > = \Gamma \sqrt{\mu - \mu_c}, \tag{A7}
\]

where the prefactor \( \Gamma = \sqrt{\frac{a}{\mu_c}} \sqrt{\frac{4(\lambda_i - 1)}{(a-1)^2 \log 2}} \). On the other hand, the charge density yields

\[
\rho = \frac{4(\lambda_i - 1) \int_0^1 y^{2\lambda_i-3} F^2(y) dy}{(a-1)^2 \log 2} (\mu - \mu_c). \tag{A8}
\]

Another way to find the required value \( \xi(0) \) is by direct solution of the equation (29). For general value of the parameter \( \lambda_i \) it is given in terms of the hypergeometric \( 2F_1(a, b; c, z) \) functions [43] as

\[
\xi(z) = C_2 + \frac{q^2 r_0^2}{4(\lambda_i + 2)(\lambda_i + 1)\lambda_i(\lambda_i - 1)} \left[ \lambda_i(2a(\lambda_i - 1) + \lambda_i + 1)z^{2\lambda_i+4} 2F_1(1, \frac{\lambda_i}{2}; \frac{\lambda_i + 3}{2}, z^4) - (\lambda_i + 1)z^{2\lambda_i+2} 2F_1(1, \frac{\lambda_i}{2}; \frac{\lambda_i + 3}{2}, z^4) + (\lambda_i + 1)(-z^{2\lambda_i} + \lambda_i(\lambda_i - 1)C_1 \log \frac{1 - z^2}{1 + z^2}) \right ] \tag{A9}
\]

Remembering that \( \lim_{z \to 1} 2F_1(1, \frac{\lambda_i}{2}; \frac{\lambda_i + 3}{2}, z^4) = -(1 + \frac{\lambda_i}{2}) \log(1 - z^2) \) and \( \lim_{z \to 0} 2F_1(1, \frac{\lambda_i}{2}; \frac{\lambda_i + 3}{2}, z^4) = 1 \) one chooses the constants \( C_1 \) and \( C_2 \) in such a way that the solution is finite with \( \chi(1) = 0 \) and finds \( \xi(0) = C_2 \) with \( C_2 \) given by the formula (A6) above.
